Multilingual Education and Language Awareness

CHRISTINE HÉLOT

The role of languages in education is both a central and a contentious issue faced by most education systems in the world today, because many teachers have to contend with multilingual students being schooled in languages other than their mother tongues. In the face of this growing linguistic heterogeneity, language education needs to be reconceptualized away from a dominant monolingual perspective, and all teachers of all disciplines at all levels are concerned by issues related to multilingualism.

As explained by Cenoz (2009), it is not easy to define multilingual education. Traditionally, many schools have been offering second or foreign-language classes at secondary level (more recently also at primary), and the general perception has been that the more languages are offered in a school the more the school is multilingual. But as Cenoz's comprehensive continua model explains, offering foreign languages as school subjects is a weak form of multilingual education. For education to be truly bi- or multilingual, the second or foreign languages must be fully integrated in the regular syllabus and used as languages of instruction. Truly multilingual schools are

schools which exert educational effort that takes into account and builds further on the diversity of languages and literacy practices that children and youth bring to school. This means going beyond acceptance or tolerance, to cultivation of children's diverse languages (whether dominant, indigenous or immigrant, or autochthonous minority) as teaching languages. (García, Skutnabb-Kangas, & Torres-Guzmán, 2006, p. 13)

Many researchers have argued convincingly that bi- or multilingual education is the only way to educate children in the 21st century (Cenoz, 2009; García, 2009), yet how many children in the world today actually avail of such education? The paradox is that many children grow up with several languages in their family environment but, once they are at school, they are made to function like monolinguals and their multilingualism is silenced. Why is it so difficult for our schools to adapt to the growing multilingualism of our societies? Why is there so much resistance to transforming our classrooms into multilingual learning spaces?

Several reasons will be briefly outlined. The first one is historical and ideological: Most public school systems were created as part of the nation-state and meant to implement language policies based on the use of one standard, official language seen as essential for the development of national identity and social cohesion. Thus official languages became reified, "regional" or "indigenous" languages were considered as a threat to national unity and banned from schools. Only so-called "foreign" languages found a place in the curricula, as separate school subjects and taught according to the same principles as those applied to classical languages (such as ancient Greek or Latin).

The second reason is that, despite all the research on bilingual education published since the 1960s, there are still a lot of misconceptions about bi- and multilingualism. Many educators believe learning can only take place in a monolingual mode, and speaking a different language at home can be detrimental to the acquisition of the school language.

In other words, multilingualism is still conceptualized by mainstream teachers as a problem rather than as a resource or a right. This happens more specifically in the case of minority or heritage languages, much less so when dominant European languages are part of bilingual education (Hélot, 2007). Consequently, a dichotomous perception of bilingual education has developed where elite bilingualism is seen as a major advantage and minority bilingualism as a disadvantage or, worse, as a handicap. This is the reason why, in many countries, educational policies regarding speakers of minority languages tend to be envisaged from a deficit perspective, dismissing their linguistic and cultural capital, and leading to compensatory pedagogical approaches which focus mainly on the acquisition of the language of schooling and at best pay lip service to bi- or multilingualism.

The third reason concerns the continuing lack of awareness of linguistic and cultural diversity on the part of most teachers in mainstream classrooms who lack adequate language education and basic knowledge about bi- or multilingual practices. Primary teachers, for example, are required to focus on literacy acquisition in the school language (in the singular) and secondary language teachers tend to be specialists of one foreign language only. Other curriculum subject teachers usually do not think language diversity issues are their concern.

Because a multiplicity of languages can now be found within a single classroom, there are no simple answers to deal with the various challenges explained above. Teachers cannot be expected to know all the languages of their multilingual students, formal approaches to bilingual education for all students is impractical in many contexts worldwide and would require a massive investment in teacher education, and, last but not least, it is a rather complex matter to change the monolingual habitus of our school systems. But, at the same time, we clearly need to question the monolingual ideology which pervades our education systems and which also affects bilingual education (García, 2009). We know how crucial it is for bi- and multilingual students' identity and their language development not only to acknowledge their first languages but also to include these languages in the learning process. We also know that some students (bilingual as well as monolingual) do need support in the acquisition of the school language, and that monolingual students should develop a plurilingual repertoire and be exposed to linguistic and cultural diversity. In other words all pupils should be given the chance to learn more languages and to understand the role of languages in our multilingual societies.

Language awareness (LA) and knowledge about language (KAL), as interdisciplinary and related fields of inquiry in language education, address such issues. The best introduction to this domain is Cenoz and Hornberger (2008). Their volume provides an extensive review of recent research carried out in different parts of the world and shows how LA and KAL differ from foreign-language learning, how they allow educators to expand beyond school languages, to legitimize the use of minority languages at school, and to raise awareness of cultural and linguistic diversity. In the words of James and Garrett (1992, p. 8): "Language awareness is a person's sensitivity to and conscious awareness of the nature of language and its role in human life," whereas Cots (2008, p. 15) refers to KAL as "explicit knowledge in the form of pedagogical contents and more or less sophisticated metalanguage, which is aimed at bringing to the conscious attention of learners particular aspects of how language functions as a system and is used in society."

We shall not focus on the different connotations of the two terms, but stress that both LA and KAL are extremely useful notions to think about language education in a more integrated way, in other words to envisage together the teaching of the school language, of second or foreign languages, mother-tongue education, as well as the inclusion of minority languages in the curriculum. Indeed, Hawkins (1984) developed his "awareness of language" approach with the intent of bridging all aspects of language education, rather than teaching languages in isolation from one another, and 20 years later Edwards (2004,

p. 144) is making the same point: "lack of joined up thinking in language policy has made young people's experiences of language learning less than satisfactory."

LA is often misinterpreted by teachers, so it should be made clear that as a model of language education it does not preclude foreign-language learning but expands on it to include the social (and political) dimension of language use (Hélot, 2007). Its main goal is to support multilingualism both at the institutional level and at the individual level and to develop different attitudes toward minority-language speakers, toward linguistic and cultural diversity, and toward language use in society.

Several examples of pedagogical projects carried out in Europe, Canada, and elsewhere show that it is possible to make space in the curriculum for transdisciplinary activities based on the different languages spoken by students in a class. See for example the Multilingual Resources for Children Project (1995), EVLANG (Candelier, 2003), EOLE (Perregaux, De Goumoëns, Jeannot, & De Pietro, 2003), ELODIL (www.elodil.com), and the many projects developed by the ECML in Graz (<http://www.ecml.at/>). Other projects involve teachers working closely with parents and building on funds of knowledge to expose learners to a multiplicity of languages and cultures and to empower speakers of minority languages (Hélot & Young, 2006). Others focus on creating multilingual literacy environments for young learners (Kenner, 2004), on the use of dual-language books to help bilingual learners to explore the differences between their languages (Sneddon, 2009), or on educating teachers to use children's literature in different languages so as to create multilingual learning spaces in monolingual and bilingual classrooms (Benert & Hélot, 2010). Some of these projects involve collaborating with mediators such as bilingual teaching assistants who share the pupils' languages, or parents and siblings who act as language brokers and support mainstream teachers to include several languages in the regular classroom activities. It is through such processes that teachers can learn to feel less threatened working with languages they do not know.

One interesting example is Cummins's (2006) "identity texts," where students invest their identity in creating multimodal texts using their different languages (thus legitimizing their home languages in class), in learning to read and write in their first language alongside the school language, and in making it possible for each different language to enter the learning space of the classroom. Another creative project is that of Dagenais, Moore, Lamarre, Sabatier, & Armand (2009), who used the linguistic landscape as a pedagogical framework for LA activities: Young learners were asked to take photographs of various language signs in the environment of their school and to design LA activities based on these signs; this led them to engage with linguistic diversity in a given territory, and to reflect upon linguistic diversity and use of language in everyday life.

What we see at work in such projects is a form of engagement with languages which goes beyond focusing on form and learning a language in a decontextualized fashion; emphasis is instead placed on understanding language use in its social context and on authentic use of language and languages as a basis for LA activities. In other words the ultimate aim of LA activities is to understand the nature and function of language in human life and what language does for us and for others.

One last point should be made in relation to teacher education. As Hawkins (1984) insisted, one of the main challenges for the LA movement was to provide adequate preparation for teachers. Referring to "multilingual language awareness (MLA)," García (2008, p. 393) stresses that it must be at the core of all teacher-education programs, because "it behooves teacher educators to put language difference at the centre of the educational enterprise." MLA should indeed be integrated throughout the entire teacher-education curriculum, but this is proving a real challenge in the face of educational policies that focus on school-based language competence and normative evaluations, and which refuse to acknowledge the impact on schools of growing social inequalities. However, in our

experience even a short introductory course on LA can help teachers to make a difference, to become agents of change in their schools (Hélot, 2010), and to transform their classrooms into spaces where a multiplicity of languages and cultures can strive together. MLA for teachers is crucial if we want multilingual language use to become normalized in our classrooms, and each school to develop its own language policy, taking into consideration the languages of newcomers, those of minority speakers, those of bilingual students, and the language(s) of schooling.

Multilingual Education in Africa

KATHLEEN HEUGH

Introduction

Approximately 2,100 (30% of the world's) languages are spoken in Africa (Lewis, 2009), with multilingualism a defining characteristic of the continent. Multilingual repertoires in Africa are acquired informally and in formal education, within communities and across regions. Multilingual proficiencies develop horizontally across several linguistic systems (continua of languages) and also vertically as multiple languages learnt in parallel, in schools. Although much of the literature portrays Africa as a continent without literacy and education as understood in the West or North, it has overlooked literatures in multiple languages, scripts, and symbolic systems which developed from hieroglyphics from the north and philosophical traditions from the south (e.g., Egyptian, Ethiopian, Bassa, Meriotic, Vai, Mende, Nsibidi, Akan, Adinkra, Wabuti, and Tifinagh) (Bekerie, 1996; Battestini, 1997; Ki-Zerbo, 2003, p. 31). Also overlooked are the multilingual scholarly traditions of the 12th to 19th centuries across the Sahel from Mali to Nigeria.

Historical Continuum of Multilingual Education in Africa

Multilingual education systems span at least six historical phases which include multiple languages and literary texts. Three of these periods preceded the late 19th-century European partition of Africa. The first was in Egypt, found in the bilingual (Greek and Egyptian) text written in three scripts (hieroglyphics, Demotic, and Greek) on the Rosetta Stone (dated about 200 BC). The second period appears in the Horn of Africa with the development and spread of ancient Ethiopic script (Ge'ez) from the 2nd to 14th centuries AD. The third was associated with the spread of Islam across North and West Africa from the 7th to 12th centuries. The rise of Islam and spread of Arabic was accompanied by education, literacy, and literature in several African languages transcribed in Arabic script, known as Ajami. This is evidenced in the estimated 700,000 manuscripts from the university mosques of Timbuktu, which accommodated 25,000 students by the 12th century AD (Timbuktu Education Foundation, 2002), and also in less well-known libraries to the 19th century (e.g., in Kano, Northern Nigeria). The partition of Africa after the Berlin Conference of 1884–5 was accompanied by fundamental changes to existing practices of education and literacy. Earlier systems were discarded and replaced with European models using the Latin script. While education has been predominantly geared toward a single language, usually the (former) colonial language, a further three phases of multilingual education have coexisted with more dominant monolingual European-based systems. The fourth phase of multilingual education coincided with the promotion of African languages in primary schools and the development of orthographies and translations of the Bible by missionaries in “Anglophone” colonies. This approach has been largely discontinued since the 1960s after which time postcolonial governments took control of mainstream education and favored earlier introduction of the English medium in former British colonies. A fifth phase included a mainstreaming of multilingual education in unpopular political regimes

2 MULTILINGUAL EDUCATION IN AFRICA

in South Africa and Namibia (1955–75), and Guinea Conakry (1968–84). This phase also included experimental, usually nonformal, bilingual early primary education in several language combinations, in West African countries. The latest phase, the sixth, has coincided with international educational and political changes since the 1990 UNESCO Conference “Education for All” in Jomtien, and has been taken up explicitly in post-apartheid South Africa, and in Eritrea and Ethiopia (Alidou et al., 2006; Benson, Heugh, Bogale, & Gebre Yohannes, 2010).

Numerous studies, independent of colonial administrations, including the Phelps-Stokes Commissions of the 1920s (Jones, 1922) and *The Report on the Use of Vernacular Languages in Education* (UNESCO, 1953) advocated the use of African languages in primary education. However, for more than a century the imprint of colonization has been so significant that systems that are geared toward a single European language (sub-Saharan) or Arabic (North Africa) have come to dominate education (e.g., Bamgbose, 2000). Late 19th- and early 20th-century colonial administration was either insensitive or antagonistic toward precolonial education. Instead, European educational templates were placed over earlier systems. While British administration displayed insensitivity, “Francophone” administration prohibited literature in scripts other than Latin or in languages other than French (Alidou, 2004). Thus, centuries of scholarly practices and literatures of West Africa were rendered invisible (see Skutnabb-Kangas, 2000). Monolingual education in French was provided only for a small minority of the elite in “Francophone” colonies (approximately half of sub-Saharan Africa). Similar policies were adopted in “Lusophone” and “Hispanophone” colonies. The British, however, allowed Christian missionary organizations to establish primary schools for small elites, using local languages to evangelize communities and for (early) primary education, but followed by English-medium education after four to six years. Prior to the Berlin Conference, indigenous and religious education in Africa and Europe reached similarly limited sectors of the broader society. While in Europe education was extended to the masses from the late 19th century, the colonial powers did not extend education to their “colonies” when they replaced African systems. It was from this point that the gap between literacy and education in Europe and Africa began to widen. Colonial education introduced mainly monolingual education in exogenous languages for limited numbers of students who would find employment in colonial administration (see Heugh, 2009).

Postcolonial Practices

Most countries reclaimed political, but not educational, independence from Europe in the late 1950s and 1960s. Neocolonial practices continued to privilege exogenous models, however, accompanied by a perception that modernity could be delivered only through international languages, and this has characterized most postindependent formal, state education. However, low academic achievement and large-scale attrition through primary school in the “international language of wider communication” (Wolff, 2006) is evident in every country except possibly Zimbabwe prior to 1990. African languages, which include local, regional, and cross-border lingua francas, have been systematically removed from formal education before students have developed adequate proficiency in the international language.

For sound educational reasons, longer use of African languages in education has been encouraged by African scholars, for example through The Language Plan of Action for Africa accepted by the Organization of African Unity (OAU, 1986; Mateene, 1999) and the Asmara Declaration on African Languages and Literature (Asmara Declaration, 2000), and, more recently, via the Academy of African Languages (ACALAN). In some countries,

notably Tanzania, Malawi, and, for a short period, Somalia, a single African language (Kiswahili, Chichewa, and Somali) has been advanced as the dominant language of (early) primary education, followed by a transition to English medium. While this demonstrates the efficacy of dominant African languages in education, it has also disadvantaged other smaller language communities, particularly in Tanzania and Malawi. The prioritization of Arabic in North African countries has similarly resulted in the educational marginalization of many indigenous communities from Morocco to the Sudan (Kabel, 2010).

There have been several attempts to reprioritize African languages in nonformal, bi/multilingual literacy programs in West African countries, for example in Cameroon (Tadadjeu & Chiato, 2005), Niger (Alidou et al., 2006), and Burkina Faso (Ilboudo & Nikiéma, 2010). The Six Year Primary Project in Nigeria demonstrated successful Yoruba and English bilingual education (Bamgbose, 2000), but the findings were not taken up through the system. In Mali, the use of African languages alongside French was supported by the Minister of Education in the late 1980s with the introduction of experimental bilingual primary education, *pédagogie convergente*, involving home language and French. This has been expanded to include the use of 11 Malian languages in over 2,000 schools (Traoré, 2001).

Multilingual education was mainstreamed across systems in a few cases during the fifth phase: in South Africa and Namibia between 1955 and 1975; and in Guinea Conakry between 1968 and 1984. In each of these, multilingual education was associated with unacceptable divisive political agendas and rejected through civil rebellion (Heugh, 1999; White Oyler, 2001; Alidou et al., 2006). In Southern Africa, early missionary development of orthographies and primary school education in African languages, although discontinued in Zambia, Zimbabwe, Botswana, and Swaziland, was pursued in South Africa and Namibia (under South African administration from 1918 to 1990). The multilingual education system included bilingual education in Afrikaans and English for speakers of these languages, and a trilingual system for speakers of African languages (the mother tongue, Afrikaans, and English). Seven South African and five Namibian languages, in addition to Afrikaans and English, were developed for use as languages of instruction for eight years of primary school. We now know from cognitive neuroscience and psycholinguistics (see Abadzi, 2006) that this system offered optimal opportunities for students to develop high levels of bi/trilingualism and high levels of academic achievement. However, the system was understood to be integral to separate and unequal development. For this reason, despite significant increases in the educational achievement of African students in secondary school exit examinations from 1955 (43.5% pass rate) to 1976 (83.5% pass rate), it was rejected by African students and parents, along with the requirement to study some subjects in Afrikaans, in 1976 (Heugh, 1999, p. 302).

The last hundred years of education have been unsuccessful for most students. Those who have succeeded have either been a socioeconomically privileged minority of students in monolingual (French, English, or Portuguese) programs or those from a wider socioeconomic stratum educated in the comparatively few bi/multilingual education programs. Enrolment in secondary education remains below 50% across the continent, with most primary school children exiting prior to the end of primary school (Bamgbose, 2000).

Recent Developments and Research Findings

UNESCO's concerns for universal primary education, literacy, and good-quality education have been embraced by most countries since the 1990 conference in Jomtien, along with a renewed interest in the educational advantages of African languages in education (e.g., Alidou et al., 2006). Significant political change in several countries coincided with attempted

transformation of education after 1990, particularly in Eritrea, Ethiopia, and South Africa. New education policy has included an explicit focus on multilingual education, but with differing degrees of implementation in each of these contexts. The approaches in Ethiopia and South Africa over the last 15 years are compared below because they offer valuable lessons about effective and ineffective system-wide implementation, costs, and risks.

In South Africa, despite constitutional and policy commitment to additive bi-/multilingual education, the practice has reverted to early-exit transitional bilingual education along with an expensive but unsuccessful attempt to implement constructivist, outcomes-based curriculum between 1997 and 2009 (e.g., Heugh, 2009). South African education authorities argue that multilingual education is too costly to implement and that parents prefer English rather than mother-tongue or bilingual education. Neither argument stands up to scrutiny. The additive bi-/multilingual policy offers high-level proficiency in two languages, not one or the other. The National Sociolinguistic Survey conducted by the Pan South African Language Board in 2000 shows that 88% of adults over the age of 15 indicate a preference for good provision of mother tongue and English, that is, bilingual education. More than one-third (37%) indicate a preference for mother-tongue education only; and only 12% of people wish for English-only education. Since 9% of people were home language speakers of English in 2000, this suggests that only an additional 3% of people with languages other than English advocated English-only education (PANSALB, 2000, pp. 118–21). The argument over the cost of linguistically diverse systems lacks substance since multilingual education provided for African children under apartheid was resourced with a fraction of the expenditure directed toward bilingual education for English- and Afrikaans-speaking children (Heugh, 2002; Alidou et al., 2006), and this is similarly evident in contemporary Ethiopia (below) (see also Grin, 2005).

System-wide assessment at provincial and national levels in South Africa showed a steady decline in academic achievement from 1976, when eight years of mother-tongue-medium (MTM) education were reduced to four. Despite considerable investment in new policy, curriculum, and teaching materials after 1994, the switch to English medium occurs even earlier (before or by third grade). Student (under)achievement has continued in a negative direction, with fewer students achieving literacy, and low levels of secondary school exit achievement (see below).

The Ethiopian example is different. Education policy in 1994 established a principle of bi-/trilingual education for all students. This includes eight years of MTM education, plus the learning of English as a subject from the first year of school, plus Amharic as a second language for the 73% of school pupils from other language communities. Although this has not been implemented evenly across the country, the 11 regional education bureaus have been systematic and it is possible through three sets of systemic assessment (in 2000, 2004, and 2008) to track correlations between the different iterations of multilingual policy implementation and student achievement. The data have relevance for other linguistically diverse educational contexts where authorities have balked at implementing multilingual systems.

Earlier African studies have shown that under optimal conditions, such as in the well-resourced Six Year Primary Project for Yoruba-speaking children in Nigeria, six years of MTM are sufficient for students to make a successful transition to English-medium education in the seventh year (e.g., Bamgbose, 2000). In less favorable conditions, such as the poorly funded apartheid system of mother-tongue education for African children, eight years of MTM resulted in the highest level of student achievement of African students to date.

The implementation of MTM across Ethiopia, in different iterations (for four, six, or eight years) depending upon the region, accompanied by system-wide assessment, offers an opportunity to evaluate the efficacy of contemporary MTM-bi-/trilingual education,

horizontally across a country, and longitudinally. Briefly, the Ethiopian data show a correlation between the number of years of MTM plus Amharic as a second language, plus English as a foreign language (FL). Students with the greatest number of years (eight) of MTM in the trilingual school system achieve the highest scores across the curriculum. Those with the fewest years of MTM (zero) achieve the lowest scores. There is a clear incline of achievement with increasing numbers of years of MTM plus L2 plus English FL. There is also a correlation between students who achieve higher results in mathematics and science and those who have the highest number of years of MTM plus Amharic plus English (Heugh & Skutnabb-Kangas, 2010).

Comparisons between the most recent South African and Ethiopian approaches to multilingual education may be useful for resource-poor contexts. Multilingual education is often considered to be too expensive to implement, and this is a reason advanced by South African authorities for not proceeding with implementation in 11 languages, even though South Africa is comparatively wealthy. Ethiopia is one of the poorest countries in the world, yet a multilingual education system was implemented in at least 23 languages between 1994 and 2006, literally starting from scratch in many languages. Ethiopia succeeded by decentralizing language and materials development to the regional education authorities, and this encouraged local expertise in language development, textbook publishing, and community participation in education. Students are provided with low-cost textbooks and, although there are shortages, most pupils have at least one textbook to take home each day. In contrast, commercial publishing of school books in South Africa produces prohibitively expensive books, even though these are mostly in English rather than in African languages. Because of cost and fear of students damaging or losing them, they are seldom allowed access to these materials.

Multilingual education in Ethiopia has been successful at multiple levels: language (including orthographic) development, teacher education, curriculum, materials production, assessment, and student outcomes. However, it is currently at risk from the unintended consequences of reverse planning and the “washback effect” of a newer implicit policy which prioritizes the role of English. Even though Ethiopia was never colonized and therefore has no historical commitment to English, the country is susceptible to the pressures of globalization and the internationalization of English. The pressure toward English has escalated since 2002. This has resulted in a series of costly initiatives to improve the English-language skills of teachers and provide televised teaching in secondary school through English. The effect has been to erode confidence in Ethiopian languages as conduits of successful education, and to reduce the number of years of MTM in several regions. The most recent systemic assessment in 2008 shows that the increasing emphasis toward English is followed, as it was earlier in South Africa, by lower overall academic achievement of students, particularly in mathematics—and ironically also in English.

Conclusion

The history of education in Africa demonstrates that multilingual indigenous systems have produced successful educational outcomes and literary resources, whereas monolingually driven models introduced from Europe have been largely unsuccessful. This applies as much to the use of European languages as to the use of Arabic in North Africa, as well as to Kiswahili in Tanzania, and Amharic in the Horn of Africa before 1994. After 120 years of monolingual systems which emphasize a single dominant language, more than 50% of children of school-going age remain outside of secondary school, and those who are retained through primary school exhibit low levels of literacy and numeracy (e.g., Mothibeli, 2005; Reddy, 2006). Postcolonial examples of multilingual education—in South Africa from 1955

and in Ethiopia from 1994—demonstrate that it is possible to establish and mainstream multilingual education systems which include contemporary educational curricula with MTM for at least eight years. Such systems include the teaching of an international language during the MTM years so that students have the time to develop sufficient proficiency in this language to use it for secondary or further education. It is possible to resource these even where financial resources are scarce. As is also evident in many other examples of nonformal bi-/multilingual initiatives, in Cameroon, Niger, Mali, and Burkina Faso, local expertise can be harnessed to develop learning materials in local languages within a relatively short period of time. For example, 12 languages were developed for educational use in South Africa and Namibia between 1955 and 1965; and 23 languages were similarly developed between 1990 and 2004 in Ethiopia. However, research from these last two contexts shows how the (globalized) pressure toward, and too early introduction of, English-medium education can undo successful policy within a short period of time. The impact of French, Portuguese, and Arabic elsewhere in Africa is no more positive. Education in each of these languages of wider international communication has exacerbated socioeconomic and sociopolitical gaps between small elites which have acquired high-level proficiency in these languages and the vast majority of people who have not.

Multilingual Education in Australia

BRIGITTE LAMBERT

Simply put, multilingual education refers to the teaching or learning of more than one language. In Australia, the term is widely associated with teaching programs for languages other than English (LOTEs), although English is also an additional language for many residents.

Multilingualism and therefore some form of multilingual education have always been features of life in Australia. Before the arrival of British colonists in 1788 and the establishment of English as the national language, some 260 Aboriginal languages were spoken throughout the country, and intertribal marriage meant that children learnt the languages of both parents in order to communicate with extended kinship groups and neighboring clans (Dixon, 1980). Migrants from all over the world have since added to Australia's language diversity. An analysis of the most recent census in 2006 (Clyne, Hajek, & Kipp, 2008) indicates that more than 350 languages, including Aboriginal and sign languages, now make up the resource base for multilingual education. These languages are taught and learnt in various settings with the intention of serving national, community, or individual interests.

Opportunities for formal multilingual education exist Australia-wide in government and independent schools, vocational colleges and universities, in ethnic community schools and in commercial language courses. Between them, in 2006, these institutions catered to 133 languages, including 50 Aboriginal languages (RUMACCC, 2007), taking in approximately one-third of the total language resource pool, while the rest are maintained informally, in minority communities and family networks.

Within this context arise many issues that determine the status of multilingual education in Australia and the type of language-teaching programs that are provided.

Government Policy and Provision

The development of Australia's official language policies can be divided into historical eras that reflect changing tolerance and support levels for multilingual education. These phases have been described in terms of *laissez-faire*, restrictive, and welcoming attitudes (Clyne, 1991), and as British, Australian, multicultural, Asian, and economic-interest orientations (Lo Bianco, 2009). Thus, from the colonial years to early in the 19th century, languages other than English were part of the British-based education curriculum and there were no official restrictions on teaching the languages offered in schools that had been established by other immigrant groups. Opposition to multilingual education arose with World War I when English became the marker of British allegiance and led to the closure of community schools, notably those teaching German. Similarly, the assertion of Australian identity following World War II favored a policy of English only and prompted the postwar assimilation drive that discouraged community language maintenance and continued to suppress indigenous languages. Yet Australia's cultural and linguistic diversity remained a reality and eventually fostered a more open mentality that in the 1970s introduced translation services and brought multilingualism to radio and television.

2 MULTILINGUAL EDUCATION IN AUSTRALIA

In 1987, the multicultural orientation produced the National Language Policy (NLP), when “for the first time in Australian history, languages other than English became the object of positive and direct attention” (Lo Bianco, 2009, p. 16). This milestone development was also a first in an English-speaking country. Nine languages were then made available on the national curriculum and in ethnic community schools—Arabic, Chinese, French, German, Modern Greek, Indonesian, Italian, Japanese, and Spanish—and programs for sign and Aboriginal languages were also introduced.

The NLP has since been superseded by other strategies. In 1992, the Australian Language and Literacy Policy (ALLP) added Aboriginal languages, Russian, Thai, and Vietnamese to the list of priority languages. The education departments in each state could then choose eight for their school curriculum. Not long after, in 1994, the National Asian Languages and Studies in Australian Schools (NALSAS) plan promoted Japanese, Mandarin, Korean, and Indonesian in the wake of establishing trade relations with Asia. This focus on Asian languages and the economic rationale for language learning have influenced LOTE planning into the 21st century.

The responsibility for multilingual education in schools falls to state and territorial authorities. LOTEs are listed as a learning strand in the curricula of the education departments in each area, but, as yet, a mandate for set teaching hours exists only in New South Wales. Since LOTE provision proceeds on local recommendations, the programs vary considerably (Lo Bianco, 2009). For example, in Victoria, the present requirement is that students receive LOTE instruction from the preparatory year to Year 10, and in Western Australia, from Years 3 to 10. Although the recommended teaching time is 150 minutes per week, more commonly, LOTE classes run for about one hour, and sometimes less. The issue of program quality is linked to what is envisaged in terms of language-learning outcomes for the students, such as fostering general language awareness or providing knowledge about the look, sound, and grammar of another language that might also have some practical application.

Bilingual or immersion teaching aimed at achieving in-depth understanding and fluency in the target language gives students the opportunity to learn some school subjects in and through both English and another language. Such immersion or content-based teaching takes place in two or more of the compulsory learning domains of Science, Mathematics, and the Arts and Humanities, and students receive a minimum of 7.5 class-time hours per week (DEECD, 2007). Student exchanges to the countries in which the LOTEs are spoken also offer immersion opportunities, but this option is not readily available for all Australian students. Full immersion programs in which all subjects are taught in the LOTE are a very recent development and tend to be parent group initiatives, like the *Deutsche Schule* in Melbourne.

A small number of bilingual programs are available in government schools for Auslan, European, Asian, and Aboriginal languages. These are located in Victoria, Australian Capital Territory, Queensland, New South Wales, and the Northern Territory. There have been signs that this might be a growing trend, with New South Wales opening four programs in 2010. However, the outlook in the Northern Territory, where bilingual schooling is particularly important to Aboriginal communities, is less than encouraging when existing programs are undermined by the government’s repeated attempts to make English the medium of instruction for the first four hours of each day (Simpson, Caffery, & McConvell, 2009).

Complementary language schools funded by the Education Departments in Victoria, New South Wales, South Australia, and the Northern Territory also offer secondary programs for about 40 languages not found in mainstream schools, including a program for distance education. About 70 languages are supported in ethnic schools throughout Australia on a part-time basis and since their aim is to maintain the culture and language

of minority groups, teaching practices from the country of origin may be used (Clyne, 2005). Consequently, the languages taught there might be perceived as belonging to the ethnic communities, that is, Greek schools for Greeks only, yet ethnic schools do have the potential to include students from all backgrounds. An innovation that has particularly served the provision of Italian is the “insertion class,” courtesy of community organizations who hire teachers to go to schools and teach the language where it fits into the timetable (Lo Bianco, 2009, p. 40).

Australian universities provide another opportunity for language learning. However, it is also a question of which languages are available and where. The number of languages on offer in 2007 was 31, covering a range from 1 to 12 languages at individual institutions (Nettlebeck et al., 2007). Most enrolments were in beginners’ courses although some students would have been able to continue with their school LOTE.

Besides deliberations about which languages to include on the educational curricula, an important consideration for government language planners is how to deliver quality programs that will lead to positive outcomes for the students. Various reports on this topic (e.g., Kleinhenz, Wilkinson, Gearon, Fernandez, & Ingvarson, 2007) point to the issues of qualified teaching staff and curriculum design, particularly in the primary school context. While dedicated teachers tend to produce good results despite adverse conditions, negative attitudes toward LOTEs and language teachers continue to detract from any incentives to enter the profession. Added to this is the belief still held by many school principals that allocating class time for language teaching interferes with the other learning content, which is considered more important. This is where bilingual programs that teach specific subjects in the LOTE offer a solution. Secondary schools and universities share the problems of resources, workload, and morale, but in these sectors the continuation of LOTE programs is also vulnerable to the motivation of students when LOTE is no longer compulsory and enrolment is voluntary. As the demand for specific languages waxes and wanes, so does the support.

Moving into the 21st century, educators have been concerned that languages in Australia are in a state of crisis and called for a rescue plan (Go8, 2007). Here attitude and motivation are important factors in developing implementation strategies. In this light, national language planners might look beyond the perceived trade advantages of language learning to the educational, cultural, and intellectual benefits (Lo Bianco, 2009, p. 64). A review of the situation has since resulted in the drafting of a new national languages curriculum that will hopefully lead to improvements (ACARA, 2011).

Multilingual Education in the Family

One aspect of multilingual education in Australia that has received scant attention in the research field is language planning in the private sphere. For many decades, the role of parents as language teachers has been indirectly addressed in investigations of the linguistic development of the bilingual child (e.g., Ronjat, 1913; Döpke, 1992). The evidence shows that the method and quality of the parents’ language input has a significant effect on the bilingual skills attained by the child. This research has filtered to the guides on raising bilingual children, which advocate that such a family undertaking requires an action plan (Baker, 1995). Indeed, before parents adapt to the role of teachers, they are language planners (Lambert, 2008).

Family language planning refers to the decisions that mothers and fathers—and sometimes grandparents—make in regard to language maintenance and language learning for their children. An assumption may be that such language questions arise only for immigrants in relation to English, but they concern families from all backgrounds, including

4 MULTILINGUAL EDUCATION IN AUSTRALIA

parents who don't share a given language. Family language planning can also involve a parent's "adopted" language, one that was acquired in the education system or by living outside Australia later in life (Saunders, 1988). Even monolingual parents who enroll their children in preschool language programs can technically qualify as language planners.

Not every parent who is capable of passing on additional languages will do so. Often they are proficient in English and choose this language for their children. Sometimes immigrant parents who need to learn English also adopt a negative stance and plan to phase out use of the minority language in the home as soon as practicable. Such decisions also constitute a language plan.

Family language planning can be divided into three phases:

1. The initial decision: "for" or "against" committing to the language transmission task.
2. Pre-planning: research and consultation about the language transmission task and assessment of the parents' expectations.
3. Implementation planning: assessment and evaluation of resources, materials, and methods to maximize the chances of successful outcomes.

While parents who commit to passing on a language generally engage in some form of planning, the extent to which they do so often depends on the availability of and access to information in the wider community. Thus the pre- and implementation planning activities may vary from a brief conversation between the parents or with friends, to repeated consultations with bilingualism professionals.

The most basic necessity is at least one parent who is fluent in the targeted transmission language. From this starting point, and depending on whether both parents share that language, either the "one person, one language" method will be used (Döpke, 1992), or both parties can join in the language transmission task. Additional support may be provided by family and friends who also use the transmission language—at bilingual playgroups, through literacy development at home, or in community programs and language classes at school—and by immersion visits to the country in which the transmission language is spoken. Not all parents will avail themselves of these resources, whether through choice or lack of accessibility, and their language transmission methods will vary accordingly.

A crucial element in the actions of family language planners is motivation. Such affective issues are first revealed at the point of the initial decision. Clearly, there are demotivational influences at work for parents who don't want to pass on their language. Sometimes their life experiences and social circumstances produce negative language attitudes, insecurities about conflict with monolingual partners, and an unwillingness to change existing language-use habits.

When parents agree on a language transmission plan, they do so with confidence that their children will achieve a certain level of bilingual skills. Their decisions are underpinned by a variety of reasons: from the wish to secure social and material advantages for their children, to maintaining communication in the wider family network, to serving their own needs. These parental "wants" can be translated as child-focused, mutually oriented, and parent-centered motives. Parents must also foresee some personal pleasure or satisfaction from the language transmission task otherwise they will not bother to begin.

Children who grow up in a multilingual household from birth were not, of course, involved in their parents' initial decision, but their attitudes become highly relevant once they realize there is a choice about which language to use. School-aged children in newly arrived migrant families might make more immediate language decisions that conflict with the plans of their parents.

The parents' actions at any stage of language transmission undertaking will be a combination of such factors as attitudes toward language maintenance, language proficiency

issues, socioeconomic background, level of education, personality, and social climate. These will be reflected in the type and effectiveness of the language transmission strategies that are adopted. For instance, a default approach arises when the parents' lack of English requires ongoing use of the minority language for family communication. This situation may be viewed negatively, but in effect it represents an immersion opportunity that can produce bilingual children and saves the parents from the embarrassment of modeling a "bad" variety of English. The *laissez-faire* strategy encourages rather than forces children to speak the transmission language when interacting with their parents (Porsche, 1983). Although this method has some merit because at the very least it leads to passive bilingual skills in the children, it tends to promote use of English. The issue here is how to motivate children to respond in kind to their parents. Some parents invert this method by permitting use of English at home in order for they themselves to learn it because they have little opportunity to do so elsewhere. The opportunistic approach is characterized by irregular input from parents, grandparents, and other family members. In such cases, parents may have been child migrants who still speak or have an interest in their first language but don't feel confident enough to use it with their children. It is not expected that this method will lead to bilingualism, but parents hope that the children still benefit in terms of language awareness and may be motivated to take up learning the language at school. In contrast, parents who commit themselves to a strategic language input plan want their children to achieve oral fluency and literacy skills in the transmission language. Usually this is because they themselves have had positive experiences with language learning and been able to capitalize on their bilingual skills in travel, study, and the workplace, and want to present their children with the same opportunities.

Parents with high expectations are more likely to plan ahead and seek advice about methods to increase the chances of successful language outcomes. Here, staying motivated becomes paramount, particularly when children don't respond as hoped. If parents are dissatisfied with their children's progress, they will need to revisit the planning steps and make any necessary adjustment to their strategy and expectations, with reference to the children's needs and wishes. Successful language outcomes also hinge on the quality of the parent-child and teacher-pupil relationships.

Family-based language teaching requires planning and application of an appropriate method. However, to be worthwhile, this undertaking should evolve as an enjoyable and rewarding experience for all family members. It is important for the wider community to be well informed about the process and challenges of raising bilingual children, so that parents who chose this language-focused lifestyle do not need to defend their decisions.

Parents in Australia now have better access to resources to help them with their language decisions than ever before. Attendances at university-run information seminars have shown marked increases; each year, there are new generations of parents and carers who seek reassurance about their language transmission plan. Parent initiatives such as bilingualism workshops and bilingual family newsletters also provide advice and moral support.

Family language planning has long contributed to Australia's multilingual profile, but has not received due recognition as an alternative domain for languages education. Today the efforts of parents are becoming more visible because their initiatives increasingly extend beyond the home to benefit the wider community as well. This is evident in bilingual playgroups, Saturday literacy programs, and language immersion schools that are set up alongside the language programs offered in the national education system. In part, this development has been prompted by dissatisfaction with the quality of languages education offered in government schools.

Family language planners support languages not found on the national curriculum. There are valuable insights to be gained from their experiences, which mirror those of "top-down" language planners. Perhaps the voices of parents should also be heard alongside those of

the language educators, community leaders, and other parties with specific policy interests who have hitherto been prominent in shaping the character of multilingual education in Australia.

Multilingual Education in China

ANWEI FENG

China has been experiencing a linguistic situation that is far more complex than it used to be a decade ago with regard to both language use and language education for both the majority Han and the 55 officially recognized indigenous minority groups. This complexity is primarily due to China's reform and modernization policies which have in the past three decades dominated the political, social, economic, and educational discourse and which have accelerated the spread of English throughout the country. With the English language being increasingly perceived as the key to modernization by policy makers and thus to life opportunities for individuals, policy documents have frequently emphasized the importance of the language, and schools and universities have robustly promoted it. As a result English, which used to be learned only as a relatively minor subject by students in secondary and tertiary institutions, has been enthusiastically pursued as a key linguistic capital by stakeholders at all levels of education and the general public. Bilingualism and bilingual education traditionally associated only with indigenous minority groups have become everyday vocabulary for the majority Han Chinese since the turn of the century. For the 55 minority groups, on the other hand, there is an increasing literature on trilingualism or multilingualism (Feng, 2007).

Historical Overview

Linguistically, for six decades under the communist government, indigenous minority groups have experienced policy changes with regard to minority language development, language use, and language education swinging between linguistic assimilation and genuine promotion of bilingualism in Mandarin Chinese and minority home languages (Dai & Dong, 1997; Zhou, 2003, 2004). The six decades are often broadly described as comprising three distinct periods. The first period from 1949 to 1957 is often called the initial developmental period when concerted efforts were made by the government and scholars/researchers to develop and promote minority languages and bilingualism. The period from 1958 to 1976, however, is usually seen as a setback era when ultra-left assimilation ideology dominated the policies and approaches in minority education. The period since 1977 is said to be the recovering or "maturing" period when bilingualism and bilingual education have been effectively promoted in the ethnic minority regions. Within the general three-distinct-period framework, many researchers and authors make more detailed analyses by subdividing them from the perspective of sociopolitical dynamics for each minority region in each period and reveal issues with regard to ideology, policy, and practice that are far more complex than the broad representation of the three periods (Zhou, 2003, 2004).

Despite political, economic, and sociocultural changes, the sociolinguistic profile of the Chinese Han majority has remained relatively stable, as ever, during the communist rule for the simple reason that Standard or Mandarin Chinese based on the Beijing dialect is the sole official language of China and its varieties are spoken by the absolute majority of the population in all domains. During the first four decades or so (with the exception of only the first few years in the Cultural Revolution from 1966 to 1976), secondary and

tertiary students were required to study a foreign language as a minor school subject—roughly Russian in the first decade and English afterwards. There is little doubt that the vast majority of Han Chinese were monolingual—that is, people who speak and write only the high variety of Chinese, called Standard or Mandarin Chinese, or people who speak only a low variety of Chinese, such as the local dialect Cantonese—with only a small percentage of bilingual exceptions, for example, diplomats or those Han Chinese who lived in a region or community dominated by an ethnic minority group. The term bilingualism, therefore, rarely appeared in the literature, policy documents, or school curricula for language education for the majority Han Chinese.

In the past two decades, however, this situation has drastically changed (Feng, 2007; Hu, 2008). Bilingualism in English and Chinese is widely seen as the key to modernization by policy makers and Chinese society as a whole. Catalytic factors, such as China's firm belief in its open-door policy, membership of the WTO (World Trade Organization) obtained in 2001, and the successful bidding and hosting of the 2008 Olympic Games have all fueled the enthusiasm to promote English at all levels and have helped to reshape China's education system. As English is widely perceived as the key to modernity and to life opportunities for individuals, it has become one of the most important school subjects. In major cities such as Shanghai and Xi'an, it is also often used as a medium of instruction or in immersion programmes in schools and universities (Knell et al., 2007; Hu, 2008). Many strong forms of bilingual education, as defined in Baker (2006), have become increasingly popular.

The impact of English–Chinese bilingual education on indigenous minority education is immeasurable. Inevitably, traditional bilingual models aiming to produce minority home language and Chinese bilinguals have become inadequate. Official policies at the state level at least have clearly included minority groups in the English promotion campaign (Feng & Sunuodula, 2009). A number of scholars such as Beckett and MacPherson (2005) have predicted that the national drive for English-language education is inevitably empowering the already powerful majority Han group, leaving indigenous minority peoples even further behind. Inside China, discussions on trilingualism to develop competence in minority home language, Chinese, and English have been on the rise, but serious challenges are posed to policy makers, researchers, and teachers on how the three languages can be appropriately dealt with in schools.

English–Chinese Bilingualism

It is hardly surprising that the literature on teaching and learning English as a Foreign Language (EFL) is huge in China as it has had a long history of English-language education (Adamson, 2004). The notion of English–Chinese bilingualism, however, has made its appearance only recently. Despite its short history, there is extraordinary diversity in terms of models used for bilingual education which are affected by regional differences in economic and sociopolitical power and people's perceptions of the English language. One approach to studying such diversity is to look, first of all, at benchmarks of English-language proficiency policy documents set out for different levels of schooling. With an institution favoring top-down approaches in China, policy documents would without doubt provide a good starting point for analyzing the dynamics between national and local policy agendas and the diversity of practices.

In 2001, three policy documents were disseminated by China's Ministry of Education to promote English-language education throughout the country. The first two specify the New English Curriculum Standards (NECS) (see Figure 1) for primary and secondary schools. The first document (Ministry of Education, 2001a) was issued to primary schools,

Figure 1 English proficiency levels from primary up to secondary school graduation (Ministry of Education, 2001a, 2001b)

stipulating that English provision was to start from Year 3 in all primary schools by the fall of 2002. On the premise that primary school leavers achieve level 2 in the language, the second (Ministry of Education, 2001b) set up specific English standards for secondary schools, with level 5 being for junior secondary school leavers and level 8 for senior secondary school leavers. Attached to the second as appendixes are specific requirements for pronunciation, vocabulary, phrases, grammar, functional and notional inventories, and even a long list of English expressions to be used in classrooms. Both documents are claimed to be applicable to all schools nationwide. Apparent in the documents is the intention to standardize teaching philosophy and approaches, even though mention is made of the diversity of pupils' backgrounds, resources, and other contextual factors.

These two NECS policy documents prescribe a seemingly elastic but linear model envisaged by policy makers. In terms of exposure to English, a typical pupil starts English learning at Primary 3, has two class hours per week in Primary 3 and Primary 4, and four class hours per week for the rest of his or her primary and secondary education. The pupil has to meet the required level to proceed to the next stage. Flexibility appears only when the pupil enters senior secondary school. However, for tertiary education, level 8 is indicated in the document as a desired level, with level 7 specified as the minimum level.

The NECS documents detailing the rationale, learning outcomes, pedagogy, and inventories of lexical and grammatical items for teaching and learning have not only provided the official benchmark for primary and secondary schools, but have also become the basis for revising the traditional National College English Syllabus which is now called College English Curriculum Requirements (Ministry of Education, 2007) for students at tertiary level. College English Education has been a huge part of tertiary education since 1985 when the first College English Syllabus was promulgated in China. There is a huge literature

about College English teaching and learning both in Chinese and English. As it is essentially a traditional EFL programme, it is not focused on here.

The third document issued in 2001 makes a short but significant “suggestion” for a new approach to English-language education at the tertiary level. Under its general title, *Guidelines for Improving the Quality of Undergraduate Teaching* (Ministry of Education, 2001c), it stipulates that within three years after the issuing of the document 5–10% of the tertiary courses for undergraduate students be conducted in English, or in another foreign language. The paragraph containing this stipulation is short but momentous for it was the first official endorsement of this strong form of bilingual education, that is, using both Chinese and English as the media of instruction. The endorsement was partly due to the long dissatisfaction of the outcome of traditional EFL teaching in the country and partly due to the increasing awareness of the research published internationally that gives evidence of the effectiveness of the content language integrated learning (CLIL) approach and immersion programmes. It was also due to the fact that many schools and universities in metropolitan areas and coastal regions had already been practicing it (Feng, 2005). The past decade has clearly seen a paradigm shift in English-language education in China from traditional EFL teaching and learning to English–Chinese bilingualism.

It is, however, worth noting that some critics argue that the use of a foreign language as a medium of instruction in fact contradicts China’s language law (*Decree 37*, 2000) which ordains that all educational institutions in China, with the exception of minority groups, must use Mandarin Chinese as the primary teaching language. This explains why critics have not only been challenging the current drive for English-language education from linguistic and cultural perspectives (Hu, 2008) but also questioning its legal status. According to Chen (2002), linguists, lawyers, and policy makers are aware of the “unlawful” situation bilingual education is in, but they argue that bilingual education is a recent phenomenon and regulations or laws governing it will follow soon.

Even though China is a country that has been traditionally characterized by centralized, top-down institutions, regional variations exist in terms of state policy implementation. The process of policy formulation at the local level in response to state policies can be rather complex and the real-world practices differ tremendously (Cortazzi & Jin, 1996). It is a commonplace observation that in most ordinary schools in cities and towns where the majority Han children attend, English starts from Primary 1, instead of Primary 3, and the allocated time for this school subject often far exceeds the class hours specified in the 2001 policy documents. Furthermore, commonly seen in schools in metropolitan areas such as Guangzhou, Shanghai, and Xi’an, and coastal cities such as Shenzhen, are vigorous experiments and applications of strong forms of bilingual education such as immersion programmes (Knell et al., 2007; Hu, 2008). Private English centers/schools and bilingual kindergartens and schools have mushroomed in economic powerhouses such as the Zhujiang Delta Region and Shanghai.

It is important to note that the popularity of learning English is not confined within the school walls. In society more generally, particularly in the economically developed east, English has quickly become a required skill for desired jobs, including civil service jobs and career advancement (Feng, 2005). This has pushed societal bilingualism in English and Chinese to an unprecedented level. In major cities such as Shanghai, parents use every means to get their children into schools with reputable English provision. Furthermore, they are constantly vigilant in finding extracurricular classes and activities at whatever cost to improve their children’s English. As Zou and Zhang (2011) observe, parents of various socioeconomic statuses have all invested heavily in their children’s English. In a society with quality English-language schools and other learning opportunities highly commercialized, access to them is no doubt in the hands of the rich. This has increased social divisiveness between the rich and the poor even in the same geographical location.

In contrast to urban cities and towns where English is robustly promoted, in under-developed rural areas it is hard to provide even the most basic foreign-language education. Many studies give evidence of the urban-rural divide (Wu, 2008). Lack of resources, lack of textbooks with appropriate content for rural children, lack of pupils' motivation to study foreign languages, and lack of parents' support are common issues reported with regard to English teaching and learning in rural schools. The most acute and telling problem is the shortage of qualified English teachers. It can be argued that the urban-rural divide which is caused by the gap between urban and rural GDP per capita incomes has been widened rather than narrowed in the last few decades (Wang, 2006). The historically intractable and ever-increasing economic and social gap makes the road toward equality extremely rocky in education in general and foreign language education in particular in rural areas.

Bi-/Tri-/Multilingualism for the Minority

Language education for minority groups in any country is inevitably more complex than that for the majority group. China's minority groups numbering more than 100,000,000 are scattered in five autonomous regions and other provinces that cover more than half of the total area of the country and border on a dozen or so neighboring countries. In the last three decades, policies and official publications have placed a high premium on the notion of "*Min-Han Jiantong*," literally mastery of both the home language and standard Chinese, as the ultimate goal of bilingual education for minority groups. For example, "*Zhuang-Han Jiantong*" (mastery of Zhuang language and standard Chinese) is stipulated in the regional policy documents as the aim for Zhuang, the largest minority group in Guangxi Zhuang Autonomous Region in China; *Zang-Han Jiantong* for Tibetans and *Yi-Han Jiantong* for the Yi nationality in southern Sichuan and Yunnan (Dai & Dong, 1997). In regions where *Min-Han Jiantong* is truly promoted, that is, when ethnic minority languages are respected, taught, and used as a medium of instruction in schools, it is common to see in published reports positive outcomes such as reduced illiteracy, increased confidence in maintaining minority languages, cultures, and identity, and improved competence in Mandarin Chinese (Zhou, 2001, 2003).

Huge investments by the government and other organizations in recent years have led to effective programs and models that aim to develop *Min-Han Jiantong* bilinguals (Zhou, 2004). However, not surprisingly, there are many issues which have historically proved difficult to overcome. One main difficulty is usually reported to be lack of both human and material resources for bilingual education because of the fact that most minority dominated regions are rural, remote, desert, mountainous, and economically underdeveloped. To deal with this issue requires genuine efforts by all stakeholders over generations, but these efforts have not been forthcoming, even with official orders such as the *Constitution* (1982) and other state documents that guarantee language and cultural rights for minority groups. This is due to the fact that the issues are not purely geographical and economic. Despite the initial position of "*Min*"—the minority language—in *Min-Han Jiantong*, for example, research reports and analyses of official documents, perception research, and regional practices give sufficient evidence that "Chinese first," "useless minority language," "great Han mentality," and "assimilation" often dominate the official, usually at local level, and academic discourses of language provision for minority groups (Lin, 1997; Zhou, 2004). The result of the assimilation ideology is often the concerted and sometimes forceful promotion of Mandarin Chinese in schools instead of *Min-Han Jiantong* bilingualism.

With the advent of country-wide promotion of English at the turn of the century, the situation for minority bilingual education has become even more complicated. The past

few years have witnessed a growing literature on “*Sanyu Jiantong*” (mastery of three languages or trilingualism: the minority home language, Mandarin Chinese, and English) and “*Sanyu Jiaoyu*” (trilingual education). For some groups such as the Yao nationality in Guangxi and the Ewenki in Inner Mongolia, they learn and speak three languages on a daily basis, their own minority language, the dominant minority language used in the region, and Chinese. When the pupils face English, “*Duoyu Jiantong*” (multilingualism) has logically become the educational aim. “*Duoyu Jiaoyu*” (multilingual education) in the Yanbian Korean Autonomous Prefecture in Jilin, in fact, has drawn much attention in recent years because of reported success in provision of four languages in some schools there—Korean, Chinese, Japanese, and English—which are all strategically important for the region (Zhang, 2008).

Divergence with regard to local policies and practice is most outstanding when it comes to English provision for minority groups. Each minority group or minority dominated region has its own unique strategies, or lack of them, and is worth examination case by case. Take the Liangshan Yi Autonomous Prefecture in southern Sichuan, for example. The Prefecture can be divided into three zones according to language use and models for bilingual education. In the capital city and major towns where Chinese is the dominant language for communication, Chinese is used as the medium of teaching and Yi as a school subject. In isolated and deep mountains, a reverse model is used, that is, Yi as the medium of instruction with Mandarin Chinese a school subject. Schools in mixed communities can adopt either of the two models. English provision was unavailable to most Yi pupils during the nine-year compulsory education. Only those who managed to enter senior secondary school were provided with English education. In a recent survey, however, Xiao (2003) found that in some schools for minority nationalities in cities students started to learn English when they were at the junior secondary level.

Publicly accessible documents and research suggest that, while many local authorities in minority dominated or minority and majority mixed regions and communities have responded to the 2001 policies, some have hardly reacted for geographical or political reasons (Adamson & Feng, 2009). The Yanbian Korean Autonomous Prefecture in Jilin mentioned above is a clear example of the former. In Yunnan Province where 25 minority groups are scattered in different, mostly mountainous regions, efforts have been made by the provincial government to provide English for minority pupils, although resources are very limited at the present stage (Hu, 2007). In these regions, ethnic minority students are made to follow the same system as their majority counterparts, despite the fact that discrepancies exist in terms of quality and quantity of English provision and the issue of maintaining linguistic and cultural identity has become even more acute.

In some regions, however, minority children are apparently kept out of the state system. Unlike their majority counterparts in the same region, according to Olan (2007), most minority students in Xinjiang were not offered English during the nine-year compulsory education. Most of Olan’s research subjects—tertiary students—reported that they did not start learning English until they entered university. Sunuodula & Feng (2011) found that a “draft plan” issued by the Education Bureau of the Uyghur Autonomous Region in 1977 is apparently still in effect. The plan states explicitly that while majority Han children start foreign-language learning from Year 3 onward, “no foreign language courses are to be provided for schools for minority students.”

Another issue is not caused by deviation of local policies from the state policies, but by default teaching resources and the examination systems based on historical formulations. This is the issue of *Zhongjiyeu*, the language used to teach and learn English and to compile textbooks for minority pupils. Traditionally, this language has been mostly Chinese for the simple reason that most teachers of English are Chinese speakers and textbooks are compiled by Chinese writers and use Chinese as *Zhongjiyeu*. So, minority students have

to depend on their second language rather than their mother tongue to learn the third language. The first language hardly plays a role in the learning process. With the growth of the trilingual education literature, this issue has gradually drawn attention. Research in recent years, though still rather limited, has shown that the use of the mother tongue as *Zhongjiejyu* is more effective in helping minority pupils to acquire a third language (Xiao, 2003). However, Sunuodula and Feng (2011) point out that the use of the mother tongue in English learning is problematic because in high-stakes exams there are test items that require test takers to translate sentences from English to Chinese, or vice versa. Thus, discussions and research with regard to *Zhongjiejyu* make little sense unless the exam system is reformed.

Summary

Since the turn of the 21st century, China has been experiencing rapid development on all fronts, including language education. Traditional foreign-language teaching and learning have undergone fundamental changes because of various forces of globalization, the unprecedented spread of English in the wider context and, internally, vigorous official policies to promote it. The paradigm shift from EFL to English–Chinese bilingualism has effectively transformed China’s linguistic landscape particularly in economically developed areas and language provision in schools and tertiary institutions. The importance and usefulness of English, in reality or imagined, have made competence in the language a must-have for people who wish to climb up the socioeconomic ladder. Educational institutions at various levels respond actively to the official policies, some more so than others. Elite schools are often seen applying strong forms of English–Chinese bilingual education. In underdeveloped areas, however, schools also strive to respond to the policies in order not to lose out but struggle to provide even a minimal level of English education. Thus, for English–Chinese bilingual education for the majority Han group, how to address social divisiveness and the urban–rural divide caused by unequal access to the linguistic capital has become a more challenging issue than ever before.

Nationwide promotion of English has made the complex situation for minority groups even more intricate. Each minority group or minority dominated region has developed its own strategies, or lack of them, and is worth examination case by case. However, it has become apparent in the debates on language education for minority groups that provision of tri-/multilingual education seems to be the only way forward (Sunuodula & Feng, 2011). Putting the minority groups in a different system of English provision, as some suggest, or keeping them out of the system altogether and ignoring their home language would only deepen the majority and minority divide and lessen the chance for genuine equality in education and integration of China’s 56 ethnic groups. Some good practices have been reported in recent years, but to provide real tri-/multilingual education to all minority groups, many issues remain to be addressed.

Multilingual Education in Europe

JEROEN DARQUENNES

Inspired by Garcia (2009, p. 9), the term “multilingual education” is used in this entry to refer to education using more than one language as a medium of instruction in whatever combination. Such a broad approach allows for the use of multilingual education as an umbrella term to cover the wide range of existing European language-in-education policies and practices on which this entry focuses. Rather than presenting a theoretical account of multilingual education, this entry intends to provide an outline of forms of multilingual education in present-day Europe. It further highlights some challenges facing multilingual education in Europe. To conclude, it draws attention to the growing importance of the European Commission and the Council of Europe as actors in the European field of multilingual education.

Multilingual Education in Europe: An Outline

The outline of multilingual education in Europe as presented here is structured on the basis of the sociological division of the population of European states as it is commonly used in literature dealing with societal multilingualism from the point of view of the sociology of language, that is a division between the majority population and the minority population. The minority population is itself subdivided into that part of the population belonging to an indigenous minority and that part of the population belonging to an immigrant minority.

Applied to multilingual education in Europe, the three population categories sketched above allow for a distinction between (a) multilingual education aiming primarily at the majority population, (b) multilingual education aiming primarily at an indigenous minority, and (c) multilingual education aiming primarily at the immigrant population within a state. To these three categories of multilingual education a fourth one is added. It pertains to multilingual education aiming primarily at an affluent international audience. This category allows coverage of those schools scattered across Europe that are mainly attended by children of diplomats, officials working for an international organization (EU, UNESCO, NATO, etc.), or expatriates working for multinational companies.

To keep the outline of multilingual education in Europe within limits the focus is solely on multilingual education in compulsory education. No distinction is made between types of authorities (public or private) responsible for education. No systematic attention is paid to the aims or to the existence of strong, weak, monoglossic, or heteroglossic forms of multilingual education (see Baker, 2006, and Garcia, 2009, for details on such distinctions). And most examples are drawn from countries belonging to the European Union because of a lack of systematic data on multilingual education in countries outside the EU.

Multilingual Education Primarily Aiming at the Majority Population

In the majority of European states multilingual education aiming at the majority population takes the form of a type of content and language integrated learning (CLIL) or, in French, *enseignement d'une matière intégrée à une langue étrangère* (EMILE). CLIL/EMILE in Europe shows the following tendencies:

2 MULTILINGUAL EDUCATION IN EUROPE

- Because of its status as a lingua franca, the preferred CLIL language all over Europe is English, followed by French and German. Other languages (Spanish, Italian, Russian, etc.) for the time being only play a marginal role as CLIL languages (see Eurydice, 2006, pp. 18–19 for an overview of the spread of CLIL languages).
- Multilingual education has especially become established at the level of (general more than vocational) secondary education. In France, for instance, the introduction of multilingual education has taken root at the level of secondary school in the form of a so-called SELO (*section de langues européennes ou de langues orientales*). In 2007, approximately 29.5% of the *collèges* (lower secondary schools), 39.5% of the *lycées* (upper secondary schools), and 10% of the vocational schools had a SELO. Typical for a SELO is that 14- to 15-year-olds learn either a European language (German, English, Spanish, Italian, Dutch, Portuguese, Russian) or an oriental language (Arabic, Chinese, or Japanese) with at least two extra hours per week at the level of lower secondary education. Multilingual education is gradually phased in toward the end of this period. In upper secondary (age 16–18) a minimum of one hour per week in a chosen subject is devoted to multilingual education (see Bertaux, 2008, and <http://eduscol.education.fr>).
- The implementation of multilingual education at the level of primary education is a fairly recent phenomenon that goes hand in hand with the increasing popularity of multilingual education at secondary level. In the Netherlands, for instance, multilingual education started with only one secondary school in 1989. In 2002 the number of secondary schools offering multilingual education amounted to slightly more than 30. In 2010 the number of secondary schools offering multilingual education rose to 133 out of a total of approximately 1,550 schools (see <http://www.europeesplatform.nl/sf.mcgi?2629&cat=638>). The growing success of multilingual education at secondary level has pushed the government to modify the formerly restrictive legal framework for the use of languages other than Dutch or Frisian (in the province of Fryslân) as a language of instruction.

Despite the increasing popularity of multilingual education, its share in foreign-language teaching still is considerably lower than that of traditional forms of foreign-language teaching (i.e., the teaching of a foreign language as a subject). In a study published by Eurydice, it is estimated that multilingual education is offered to between 3% and 30% of pupils at primary or secondary or both (Eurydice, 2006, p. 14; see also http://eacea.ec.europa.eu/education/eurydice/index_en.php for direct access to Eurydice's Eurybase, a database with information on education systems in 31 European countries). It also needs to be noted that in some countries there is a certain reluctance to introduce multilingual education. In Iceland, for instance, the monolingual character of the country prevents multilingual education from being high on the agenda. The same is true for Portugal where the introduction of multilingual education is limited to a number of pilot projects at primary-school level. In the Flemish Community of Belgium the implementation of multilingual education is mainly hampered by a concern for the impact of CLIL on the vitality and richness of Dutch as the majority language in that part of federal Belgium.

The situation in Belgium (Flemish Community), Portugal, Iceland, and countries like Cyprus and Denmark contrasts rather sharply with countries in which the entire school population is subject to multilingual education, for instance the Grand Duchy of Luxembourg and Malta. In Malta, the national minimum curriculum obliges all schools to adopt the policy of using two languages (Maltese and English) and to develop a linguistic strategy reflecting the particular linguistic needs of its pupils and linking English more to sciences and Maltese to subjects in the field of the humanities. At the end of their entire schooling experience all students should be able to use the two national languages in an effective, precise, and confident way (see www.curriculum.gov.mt). In the Grand Duchy, the system

involves the teaching of three languages. When children enter school at preschool level, they are first taught in Luxembourgish, the home language of the large majority of the Grand Duchy's indigenous population. At primary school they learn to read and write in German. French comes in as a major component of the curriculum by the third year and then gradually becomes the medium of instruction at secondary level. Notwithstanding some shortcomings of the trilingual Luxembourgish system vis-à-vis the immigrant population (see Weber, 2009), it functions as a source of inspiration to policy makers involved in language-in-education policy all over Europe. The Grand Duchy's model, for instance, inspired the Ladin minority, one of the indigenous minorities in Italy, to develop a system in which Ladin, German, and Italian serve as school languages. The Ladin part of Italy is one of the few parts of Europe where trilingual education is offered (see Cenoz & Gorter, 2005, for an overview).

Multilingual Education Primarily Aiming at an Indigenous-Language Minority

The indigenous-language minorities account for a considerable part of Europe's linguistic and cultural diversity. The number of indigenous minority languages is estimated at approximately 60 in the 27 member states of the EU and at approximately 150 in the whole of Europe. The indigenous minorities are characterized by differences concerning their size (next to the 6.5 million Catalans in Spain there are approximately 100 Livonians in Latvia), differences concerning the spread of the minority language (the Welsh use a unique minority language whereas Catalan is used in Catalonia and on the Balearic Islands as well as in Sardinia and France), and differences concerning social organization and power (the well-organized and largely autonomous German minority in South Tyrol contrasts sharply with the situation of the Aromanians in Greece). The forms of social organization and power strongly influence the way in which education for the minority is organized. As a consequence they also have a large impact on the way in which education in the minority language can help to halt or even reverse the process of societal language shift that—albeit to varying degrees—characterizes each of Europe's indigenous minorities.

Looking at the position of the minority language in compulsory education in indigenous minority settings one is confronted with situations in which the minority language is totally absent. Numerous situations exist in which the minority language is taught as a subject. And in other cases the minority language serves as the main language of instruction or as one of the languages of instruction in a form of multilingual education (see the online regional dossiers of the Mercator European Research Centre on Multilingualism and Language Learning for examples at www.mercator-research.eu; see also <http://www.mercator-research.eu/publications> for downloadable publications on issues related to minority-language education).

Focusing on multilingual education in indigenous minority settings, the following tendencies can be observed:

- In the majority of cases the minority language and the language of the surrounding majority are used as languages of instruction. Other languages are taught as a subject. That is the case, for instance, in Lithuanian–Russian schools in Lithuania (European Commission, 2004, p. 205).
- Multilingual education is mostly offered at the level of kindergarten and primary school and less at the level of secondary education. A case in point is that of the German minority in Hungary. In 1999/2000 a total number of 284 primary schools and only 4 secondary schools offered multilingual education in German and Hungarian (European Commission, 2004, pp. 119–20).

- Systems with a strong share of multilingual education at all levels of compulsory education are mainly to be found in the context of indigenous minorities with a strong political autonomy or large powers in the field of education. In the autonomous Valle d'Aosta region in Italy, for example, Italian–French bilingual education was introduced at kindergarten in 1983, at primary school in 1988 and at middle school (age 10–13) in 1994 (Garcia, 2009, p. 300). In the Basque Autonomous Country, language-schooling model B uses both Basque and Spanish as languages of instruction at primary and secondary level for approximately 50% of school time (Cenoz, 2009, p. 50).

It can further be noted that language-in-education policy makers and researchers active in the field of minority languages in the European context are often at the forefront of developing alternatives to existing forms of multilingual education. They are not only eager to experiment with forms of trilingual education (see recent developments in Fryslân where English is used next to Frisian and Dutch). They also try to adapt the didactics of CLIL to the actual multiple discursive practices of multilingual persons in language-minority surroundings. A good example is the development of a so-called *didactique intégrée* in Valle d'Aosta that intends to capitalize on the natural occurrence of multiple discursive practices in order to transmit linguistic skills (see Cavalli, 2005). And in the Basque Autonomous Country policy makers and researchers in recent years have increasingly focused on the adaptation of the Basque educational system to the increased presence of immigrants in Basque society (Cenoz, 2009, pp. 77–83).

Multilingual Education Primarily Aiming at Immigrant Minorities

As described by Extra (2009), there have always been speakers of immigrant minority languages in Europe. As community languages spoken on a wide scale, however, these languages have only emerged in the second half of the twentieth century. Since especially in the industrialized northern, southern and western European countries the number of immigrants is still growing, the school population is becoming ever more multicultural and multilingual. This phenomenon poses an increasing challenge to policy makers in the field of education.

Large contrasts exist in the way European countries adapt or re-adapt their education policies and especially their language-in-education policies to the increasingly multilingual and multicultural character of the school population. In general, a balance is sought between, on the one hand, an emphasis on learning (in) the language that is the majority language of the country or region in which the immigrants reside, and, on the other hand, the integration of immigrant minority languages in the curriculum. Since the 1970s, the integration of immigrant minority languages in the curriculum is no longer meant to prepare the immigrant children for a return to their (parents') home country. It is rather meant to help the immigrant pupils overcome language-related learning difficulties.

As to the integration of the immigrant language in the school curriculum it sometimes is the case that these languages are not considered in the mainstream curriculum at all. In the UK, for example, immigrant languages are not part of the national curriculum and are taught in so-called complementary education in out-of-school hours (see Extra, 2009, p. 191). In other cases immigrant languages are considered and various forms of multilingual education arise since immigrant pupils receive one part of the curriculum in the language of their host environment and another part in the immigrant language (see, for instance, the Turkish–German bilingual primary schools in Hamburg). Particularities of immigrant language education in Europe are discussed in detail in Extra (2009), Extra and Gorter (2009), and publications related to the Multilingual Cities Project funded by the

European Cultural Foundation (Extra & Yağmur, 2004). One example might, however, help to illustrate the added value of well-wrought models of multilingual education aiming at immigrant populations in Europe: the Foyer project in Brussels.

In Brussels, 10 primary Dutch-language schools that are part of the Foyer project offer multilingual education programs for immigrants residing in Brussels. Three schools offer programs oriented to Turkish immigrant children, three to Italian immigrant children, two to Moroccan immigrant children, one to Spanish immigrant children, and one to Aramean–Turkish immigrant children. The aim of the programs is to gradually integrate the immigrant children in the host-school environment while simultaneously preserving and reinforcing the children’s mother tongue and cultural identity in kindergarten and during the first two years of primary school. The number of immigrant children is restricted to 30% of the school population. In kindergarten the immigrant children are taught 30% of the time separately in their first language and 70% of the time in Dutch together with Flemish children. In the first year of primary school they are taught 30% of the time separately in their first language, 25% of the time separately in Dutch as a second language, and 45% of the time in Dutch together with the Flemish children. From the third year of primary education onwards, the immigrant children are taught 90% of the time in Dutch in classes with Flemish children. They spend a few hours per week in their first language in separate classes and also start learning French for a few hours per week. The aim of the Foyer schools is to prepare immigrant children for Dutch-medium secondary education in Brussels (Baetens Beardsmore, 1996, pp. 466–7; Garcia, 2009, p. 231; and www.foyer.be).

The example of the Foyer project in Brussels shows how multilingual education for immigrants can help to reach objectives that are also at the center of multilingual education aiming at the affluent pupils attending European and international schools, that is raising pupils’ confidence in their own cultural identity as the backbone for their development as world citizens.

Multilingual Education Primarily Aiming at an Affluent International Audience

Currently there are 14 European schools spread over 7 countries (Belgium, Germany, Italy, Luxembourg, the Netherlands, Spain, and the United Kingdom). They are attended by a total of approximately 22,500 pupils. In the European schools, most pupils at the level of primary education have their first language as a language of instruction. A first foreign language (English, German, or French) is introduced in the first year of primary education and used as a language of instruction toward the end of primary and increasingly so in secondary education. In some cases, a third or even a fourth language of instruction comes into play in secondary education, depending on the optional subjects that are chosen (see www.eursec.eu). Mainly attended by the children of European civil servants, the European schools are considered to be elitist. The same is true for the so-called international schools—schools mainly aiming at children from European and American employees working abroad. Many international schools offer multilingual education in the language of the host country and at least another widely spread European language. The German schools abroad (*deutsche Auslandsschulen*), of which 45 out of a total of 140 were located in Europe in 2011 (see www.auslandsschulwesen.de), are one example. The French also have a large network of international schools, some of which are bilingual (see www.aefe.fr). De Mejía (2002) and Carder (2007) provide more detailed information on international schools. Additional information can also be found on the Web site of the Council of International Schools (www.cois.org).

Challenges Facing Multilingual Education in Europe

As multilingual education in Europe gains momentum, problems are being encountered that need to be properly addressed so as not to endanger its further expansion (Baetens Beardsmore, 2009, pp. 213–16). First of all it is proving difficult to find teachers who are qualified to teach specific subject matter in the target language of multilingual education. Teacher training offering a combination of language and content in most of the European languages is still in its infancy. There is, further, a lack of adequate teaching materials and uncertainty on how to assess the language side of non-linguistic content. The fact that in many cases there is not yet any continuity of multilingual education at all levels of education is especially problematic in such indigenous minority settings where the intergenerational continuity of the minority language largely depends on education. In contexts where a unique indigenous minority language is spoken a lack of standardization in that language also hampers the development of (multilingual) education. Policy makers and language-education professionals active all over Europe are aware of the challenges facing multilingual education in Europe. Supranational institutions such as the European Commission and the Council of Europe encourage them to join forces to meet those challenges.

Multilingual Education and the Supranational European Level

Both the Council of Europe (more specifically its language policy division and the European Centre for Modern Languages in Graz; see www.coe.int/lang and www.ecml.at) and the European Commission (more specifically the Directorate General that covers the thematic areas of Education and Culture) have put considerable efforts in documenting the various forms of multilingual education that have colored Europe's educational landscape since ancient times (see Glyn Lewis, 1979). They promote the exchange of good practices in multilingual education through the funding of projects. And they also give shape to language-in-education policy objectives. The Council of Europe promotes the individual development of a plurilingual repertoire that includes different types of competences and different languages and language varieties at different levels of proficiency (see http://www.coe.int/t/dg4/linguistic/Profils1_EN.asp for information on European-language education policy profiles). The European Commission promotes individual multilingualism in the sense that every citizen should have practical skills in (at least) two languages in addition to his or her mother tongue. Clearly, (multilingual) education is seen as the main road toward individual multilingualism or the acquisition of a plurilingual repertoire. The Council of Europe especially lends its member states a hand in that it has developed a *Guide for the Development of Language Policies in Europe* that was updated in 2007. This guide enables states and regions to analyze both the strengths and the weaknesses of their language-in-education policy. If states (or regions with powers in the field of education) so wish, the Council of Europe transfers the evaluation report to a team of experts that provides noncommittal feedback. In this context it needs to be stressed that the operation procedure of the Council and the Commission is one of consensual persuasion and that neither the Council nor the Commission can exert any direct influence on the member states in the field of education. This means that the member states are—at least theoretically—not obliged to implement proposals emanating from Strasbourg or Brussels. In practice, however, there is a clear tendency among the member states to—slowly, yet in the majority of cases also decisively—adjust national language-in-education policies to the policy initiatives taken at the supranational European level (see Baetens Beardsmore, 2009, for a more thorough discussion). A further spread of multilingual education in Europe therefore seems to be more than likely in the near future.

Multilingual Education in India

AJIT K. MOHANTY

Introduction

Synthesis of diverse cultural influences and religious traditions and coexistence of many languages complementing different spheres of public activity have remained distinctive features of Indian society. The 2001 Census Survey of India listed over 6,600 mother tongue (MT) declarations, which were rationalized into 3,592 MTs. The Census grouped the MTs into 122 major languages each of which includes several others with distinctive regional identities as well as linguistic features. The MTs in India are linguistically classified into 300–400 languages; India ranks fourth in the world in terms of its linguistic diversity (Skutnabb-Kangas, 2000). Despite the diversity, 196 languages in India are in the endangered category (UNESCO, 2009), the highest for any country. This paradox of diversity and endangerment can be understood in the context of India's weak and somewhat inconsistent language policy in education, and its failure to translate its statutory commitments into practice. This discussion seeks to show that languages-in-education policy in India has succumbed to the dynamics of the hierarchical power relationship between languages and their speakers, privileging some and disadvantaging many. Current language education policy and practices are examined to show that they fail to support its multilingual ethos and to meet the challenges for egalitarian development of minor, minority, and dominated languages. Indian schools generally offer some teaching of multiple languages, but most of the school programs are only nominally multilingual. Some current programs of mother-tongue-based multilingual education (MLE) for tribal children are discussed.

Despite many positive features of its multilingualism, many languages in India, particularly the indigenous, tribal, and minority (ITM) languages, are subjected to social neglect and discrimination leading to their impoverishment and endangerment and loss of linguistic diversity. Such exclusion of languages is a part of the vicious circle of language disadvantage (Mohanty, Mishra, Reddy, & Ramesh, 2009) in which languages are weakened due to their limited use and the resultant weakness is cited as an excuse to justify further neglect. Institutionalized linguistic discrimination in education is particularly important since it has serious implications for language maintenance (Fishman, 1991). Apart from English and 22 official languages, few other languages find a place in school and higher education in India. In 1970, schools in India used 81 languages as medium of instruction (MI) and school subjects. This number declined to 41 in 1998. Currently, 31 languages are used as MI in primary (1 to 5), 21 in secondary (7 and 9) and 18 in higher secondary (11 and 12) grades. English has a dominant presence in all levels of education and is almost exclusively used as MI in university and technical education in India. ITM languages have a negligible presence in education. Only three to four out of over 150 tribal languages are used as MI in primary grades and none at all in higher education.

The position of languages in education reflects the structural inequalities in India's hierarchical multilingualism. In all spheres of language use, English has an exclusive position of power followed by dominant regional languages including Hindi and state majority languages. The state majority languages or vernaculars, in turn, dominate over ITM languages in all domains of social, political, economic, and educational activities.

Thus there is a double divide (Mohanty, 2010) in the linguistic hierarchy of Indian multilingualism—one between English as the elitist language of power and the dominant regional languages or vernaculars, and the other between the vernaculars and the dominated ITM languages. The two divides can be characterized as the *English–Vernacular Divide* (between the elitist and dominant languages) and the *Vernacular–Other Language Divide* (between the dominant and dominated languages). The nature and implications of the double divide have been discussed elsewhere (Mohanty, 2010; Mohanty, Panda, & Pal, 2010). It should be pointed out that such a double divide has been characteristic of Indian multilingualism at different points in history (Mohanty, 2008a) and has remained central to India’s language-in-education policy as it has evolved, particularly since British rule.

Prior to British rule, education in India started with the majority language mother tongues as MI. Formal education had little impact on the indigenous tribal minorities, whose mother tongues had no writing system and no presence in education. Higher levels of education usually involved learning one of the more prestigious languages of the elites such as Sanskrit and Persian, which were also the medium of instruction (MI) in religious texts. Thus, there was no distinction between language as a subject and as MI. The distinction started with the attempt during British rule to bring English into modern education; languages in education were marked as Vernaculars (the regional majority languages), Classical languages (Sanskrit or Persian), and English. These languages were variously used with one language as MI and multiple languages as school subjects at different levels of education. Choice of languages in education was always contested at various levels, voicing the ongoing tension between the dominant and regional languages. The dominance hierarchy of languages in India continues to be treated with ambivalence, simultaneous resistance and accommodation influencing the policy and practice of languages in education in India.

Languages-in-Education Policy and Practice in India

The place of languages in Indian polity and governance became a major issue following independence and it was hotly debated in the constituent assembly. While nationalistic (and anti-imperialistic) sentiments were high, the process of making of the Indian constitution was dominated by English-educated elites. There were many claims for languages such as Sanskrit, Hindustani, Hindi, and Bengali to be recognized as national languages—and, at the same time, English could not be rejected. The Indian constitution, which came into force in 1950, resolved the issue by incorporating a schedule of 14 official languages (which has since been severally amended to include 22 languages) instead of having any one language recognized as a national language, and by keeping English as an associate official language. The constituent assembly also failed to enforce a common school system, paving the way for continuation (and, later, proliferation) of English-medium private schools. The government schools, on the other hand, continued to be regional language (or vernacular) medium schools. Although the constitution of India made no specific provision for tribal MTs in education, the distinction was made between dominant regional languages and mother tongues of the minorities. Article 351A of the constitution called for the state and local authorities to provide “adequate facilities for instruction in the mother tongue at the primary stage of education to children belonging to minority groups.” This provision recognizes the presence of linguistic minorities, such as the tribal communities and their mother tongues. However, the constitutional promises for MT education remain to be implemented. The distinction between regional languages and minority MTs continued to be ignored in subsequent attempts to spell out languages in education. The Three Language Formula was a major initiative on this issue.

In 1957, a Three Language Formula (TLF) was announced by the government of India to deal with the uncertainties and heterogeneous practices in respect of languages in

education. It recommended use of regional language or MT as the first teaching language for five years, Hindi (in non-Hindi areas) or any other Indian language (in Hindi areas) as the second language from Grade 6 to 8, and English as the third language from Grade 3. The TLF did not distinguish between the regional language and MT and, thus, the dominant regional language was imposed on the ITM groups in a form of subtractive bilingual/multilingual education. Further, TLF was applicable only for government-sponsored schools; the private English-medium schools were free to impose their own choice and combination of languages. The TLF was modified from time to time to clarify anomalies. A major modification in 1964 mandated three languages as school subjects (regardless of the MI): (a) MT or regional language, (b) Hindi or English, and (c) one modern Indian language (including Sanskrit) or a foreign language. The third language had to be other than the ones covered under (a) and (b). A transitional bilingual/multilingual program, beginning with tribal MT as the language of teaching for the first two years and switching to regional language MI from the third year onwards, was recommended for tribal MT children. This was tried as a *bilingual transfer model* in some experimental programs initiated by the Central Institute of Indian Languages and subsequently discontinued without much evaluation (see Mohanty, 1989, for discussion). The 1964 modification of the TLF sought to deal with resistance to the imposition of Hindi in non-Hindi areas and paved the way for English to replace Hindi as the second language subject. The TLF was modified several times and interpreted variously in different states. Gradually the dominant majority language of each state came to be used as MI in government schools for all children regardless of their MT, and English replaced Hindi as the second language subject.

The TLF was not advanced as a policy framework; it was a formula to balance between pressures for and against the relative dominance of Hindi and English and the role of the state majority languages and MTs. English was treated with ambivalence following the end of British rule and, at the same time, dominance of Hindi could not be accepted in the South Indian states. The dominance of state majority languages was accepted partly because the marginalized tribal and minority MT users remained powerless and voiceless—with some exceptions, as in case of Bodo and Santali, two tribal languages whose speakers asserted their linguistic rights by engaging in prolonged language movements to have the languages recognized as official languages. In general, the TLF with all its modifications and interpretations did not have much impact apart from contributing to widening the English–Vernacular and Vernacular–Other language divides. In this situation of such ambiguities and uncertainties, state-sponsored public education remains chaotic and multilingual only in a nominal sense.

Multilingual Education in India: Nominal and Experimental Programs

The state majority languages remain the language of teaching or MI in the school programs whereas English is widely used as MI for university-level education. English as a language subject has a dominant presence in the school curriculum. In most cases, at least one other language is taught as a school subject. Schools generally reflect the grassroots-level linguistic diversity with children of different language backgrounds in the same classroom. Thus, education in India is multilingual in a weak sense: multiple languages are used as MI in different stages of education, languages form a part of the school curriculum, and within-classroom diversity often necessitates informal use of multiple languages for communication. Thus, one can point to three patterns of education somewhat responsive to India's multilingual diversity: Informal Multilingual Education, Formal Multilingual Education with a Single MI, and Formal Multilingual Education with Multiple MI.

Informal multilingual classrooms seek to support different MT children with inadequate proficiency in the MI. In the *support bilingual classrooms*, teachers use children's MT along with the formal MI to enhance their comprehension. For example, teachers in some English-medium schools, particularly those for the lower economic strata, use a vernacular MT (such as Hindi or Oriya) as a scaffolding device (Mohanty et al., 2010); English texts are read and then explained in the children's MT. In *partial bilingual type of informal multilingual classrooms*, children generally use their MT (such as a tribal language) whereas teachers primarily use the MI, which is the majority state language, often utilizing a simplified register of MI since they do not know the MT of the children.

Formal multilingual education programs with single MI usually have one dominant language as the language of teaching (except for language subjects). These include *majority-language MT programs* in which a regional or state majority language is used as the MI and other languages are taught as school subjects. These are MT-medium programs for the majority children and forced submersion programs in a non-MT medium for ITM children with subtractive effect on their MT. These programs lead to poor educational performance, capability deprivation, and poverty for the ITM communities (Mohanty, 2008b). The private English-medium schools offer *non-MT-medium programs* in a single language, English, which is not the MT for the children.

Formal multilingual education programs in multiple MI mostly use two languages for teaching. *Simultaneous dual-language MI programs*, such as the government Kendriya Vidyalaya or Central Schools, use English and Hindi simultaneously as teaching languages—English for mathematics, science, and English subjects, and Hindi for social studies and Hindi subjects. The two languages are used as MI regardless of children's MT. *Successive dual-language MI programs* combine education in different levels each with a different language as MI. Primary to university-level public education in India taken together can be described as a *successive dual-language MI program*—majority regional-language MI at school levels and English (occasionally Hindi) MI at university level. A third subtype of formal multilingual education with multiple languages as MI is the *transitional bilingual education programs for minority children*, which begin with the use of a minority (tribal) MT as MI for about two to four years, during which oral communicative competence is sought to be developed in the regional majority language. There is a progressive decline in the use of MT as MI and by the fourth year the regional language become the sole MI. One such program, called bilingual transfer model, was discussed earlier. Its objective was smooth transition of ITM children into the mainstream majority-language MI programs, leading to soft assimilation and weakening of the minority MTs (Mohanty, 1989).

Clearly, the above programs in Indian education fail to meet the requirements of multilingual education; there is no systematic use of multiple languages as MI, nor do they target development of high levels of multilingual proficiency. These programs hardly offer any support to the weaker languages. Imposition of the majority language as MI on ITM children and English MI for all children in private English-medium schools have a common subtractive impact on children's MT. Thus, educational programs in India offer only weak and surface forms of multilingual education. The constitutional commitments are not honored and the attempted policy formulations including the TLF have failed to address the basic issues in India's hierarchical multilingualism, characterized by the double divide. The English–Vernacular divide is politically negotiated through simultaneous preference for and rejection of English as well as Hindi (and other regional majority languages), effectively leading to supremacy of English in education and other domains. The Vernacular–Other language divide, on the other hand, has led to progressive marginalization of ITM languages and their exclusion from education. Some recent developments in education, however, have begun to address the issue of marginalization and poor educational achievement of the ITM children, recognizing the need for MT-based multilingual education (MLE).

MT-Based MLE in India

As has been noted, the nominal forms of multilingual education in India hardly meet the requirements of developing proficiency in multiple languages—MT, languages for regional- and national-level communication, and international language for wider communication. This requirement means development of multilingual proficiency in two or three languages in the case of majority-language speakers. Education of ITM children, on the other hand, needs to develop proficiency in tribal/minority MT, state majority language, Hindi (in non-Hindi states), and English. Experimental programs of mother-tongue-based multilingual education (MLE) have started for tribal MT children in two states in India, Andhra Pradesh and Orissa, with effect from 2004 and 2006, respectively. Andhra Pradesh started MLE in 240 schools for eight tribal MTs and Orissa in 195 schools for ten tribal MTs (see Mohanty et al., 2009 for details). These programs involve use of MT as MI as well as for literacy development from Grade 1. The state majority language, Telugu in Andhra Pradesh and Oriya in Orissa, is used from Grade 2 for development of oral communicative proficiency, from Grade 3 for development of reading and writing skills, and from Grade 4 as a partial MI along with the MT. The MLE programs follow the common state curriculum with emphasis on culture-specific content. English language as a subject is introduced in the program as per state practices—from Grade 2 in Andhra Pradesh and Grade 3 in Orissa. The MLE programs envisage tribal children joining the mainstream schools in the state majority-language MI from Grade 6 onwards. The MLE programs in Orissa and Andhra Pradesh are being extended to at least 3,000 schools and some other states such as Jharkhand and Chhattisgarh are planning similar programs for tribal MT children. Besides, a special MLE program, called MLE Plus (MLE+), is in operation in eight of the MLE schools for Saora and Kui languages in Orissa. MLE+ program (Panda & Mohanty, 2009) has a special focus on cultural pedagogy with an emphasis on community participation in literacy activities and children's collaborative learning practices. Several evaluations of the MLE and MLE+ programs in India (Mohanty & Skutnabb-Kangas, 2010) show their positive effects on children's classroom achievement, attendance, and participation as well as community involvement in children's education. Despite such positive consequences, MLE programs in India are affected by "the burden of the linguistic double divide" (Mohanty, 2010). This creates pressure for accommodation of the dominant languages too early in the program instead of allowing sufficient time for adequate development of MT. This also means early transition into the dominant-language MI, ignoring the overwhelming research evidence in support of late-exit type MLE programs (Heugh & Skutnabb-Kangas, 2010).

The Indian constitutional provisions and significant policy pronouncements including the TLF are pluralistic, emphasizing MT-based education and supporting the spirit of MLE. The National Curricular Framework (NCF) (NCERT, 2005) does recommend use of MT as the language of teaching. The recent Right of Children to Free and Compulsory Education Act 2009 (RTE) passed by the Indian parliament lays down quality parameters for education of 6- to 14-year-olds as a right and mentions education in MT. However, there are contradictions and lapses in the policy documents. The NCF fails to push an agenda for MLE. It does not find any problem in continuation of English-medium schools and early teaching of English even if it recognizes the research evidence and theoretical support to the contrary. The RTE does not dispense with the dual system of private English-medium and public regional language/MT-medium schools. Further, RTE fails to guarantee MT education since Article 29(2)(f) has a weak provision that "medium of instruction shall, *as far as practicable*, be in child's mother tongue" (emphasis added). Thus, while policy provisions in respect of languages in education are rhetorical and remain far removed from actual practices, classrooms, as discussed earlier, are superficially multilingual, mostly promoting monolingual proficiency.

The gap between policy and practice in respect of languages in education raises several issues. First, the question of the language of teaching or MI remains unresolved. English MI schools are popular. English as a school subject is gaining in significance and is taught from very early grades. Most of the states in India have now brought English down to Grade 1 despite clear evidence supporting its late introduction founded on a strong development of MT proficiency. Some states like Andhra Pradesh are planning to have English-medium sections in government schools. While there is concern over providing quality education in English and bringing the power of English to the masses, good quality mother-tongue education is the missing link. Further, the dominance of English over other languages in education has subtractive effects on all other MTs.

Education of the ITMs is another pressing issue, linked to mother-tongue-based MLE. The current forms of subtractive education in a dominant language lead to school failure and high “push out” rates. The success of the current experimental programs of MLE raises some hopes. However, as pointed out, the pressure to accommodate the dominant languages early in the MT-based program raises some concerns. Further, the usual models of MLE are challenged by linguistic diversity within the classrooms with children from many MTs. It is necessary to evolve innovative models of MLE for such diverse multiple-language classrooms. More importantly, the policy and practice of multilingual education in India needs to close the gap between imposed homogenization through unregulated school practices and real-life multilingualism, which mandates a system of education that promotes multilingualism for all.

Multilingual Education in Latin America

RAINER ENRIQUE HAMEL

Bi- or multilingual education is still an exception in Latin America, as it is in many other parts of the world. Most existing models are linked to specific ethnolinguistic communities that have maintained bilingual practices over time, including that of bilingual education: indigenous peoples and immigrant communities. Both groups have preserved their ancestral languages to varying degrees which sustains their claims for bilingual education in otherwise monolingual state territories.

Indigenous and immigrant communities including their schools belong to opposite poles on the scales of extreme inequality in Latin America. Their linguistic spaces and institutions share, however, some psycho- and sociolinguistic features and challenges which allow for comparisons on a certain level of abstraction. From a macro-sociolinguistic perspective, both communities exist as bilingual enclaves in sociohistoric formations of nation-state building processes oriented towards European models of linguistic and cultural homogeneity that seek to assimilate those who are different. Therefore, any stable bilingual community—indigenous or immigrant—faces adverse sociolinguistic conditions and will have to develop specific ideological, cultural, and linguistic justifications for its bilingual domains.

It is this entry's contention that that these two educational spaces share several common problems and possible solutions, and that they could greatly benefit from an exchange of experiences and expertise across the systems. Such collaboration could foster the growth of multilingual spheres and the transition towards pluralistic nation-states where cultural and linguistic diversity would be seen as global enrichment instead of a problem.

Indigenous Education in Latin America

The sum of national census data gives the figure of slightly less than 30 million indigenous people in Latin America. Ninety percent of them live in the macro-areas of the Andes (Bolivia, the north of Chile, Ecuador, Peru, and Colombia) and Mesoamerica (Guatemala and Mexico) (Sichra, 2009).

From the beginning of the Conquest in 1492, colonialist policies materialized in education for indigenous populations through two basic approaches, a dichotomy that is still alive in our days. The first strategy aimed at linguistic and cultural assimilation through direct imposition of the European language (Spanish or Portuguese), leading to submersion or fast transitional programs; the second strategy sought subordinate preservation of indigenous peoples through slow transitional and some rare maintenance programs (Hamel, 2008a; López, 2009).

In view of previous educational failure with submersion and fast transitional programs for the indigenous population, a number of new modalities have emerged since the 1970s. In most countries, bilingual and bicultural programs gave way to the new concept of “*intercultural* bilingual education” (IBE) since the early 1990s. The two languages, content matters and competencies from indigenous funds of knowledge, as well as from national

programs, should be integrated in a culturally and pedagogically appropriate curriculum. To redress historical imbalance, children are to know and appropriate their own culture in their language first in order to build a solid base of competencies, values, and ethnic identity (intracultural component). Next they should proceed to learn content matters from the national and global societies in order to integrate knowledge and competencies from several sources (intercultural component).

Under the label of “intercultural education for all,” mainstream students should develop a relationship of mutual understanding and respect by learning about indigenous cultures; they are expected to develop positive values towards diversity through a process of knowing, recognizing, and valorizing the other cultures. In areas of significant indigenous population density ($\geq 30\%$), they should learn one of the indigenous languages (IL) of the region (in Bolivia, Mexico and some other countries; see Albó & Anaya, 2003).

On the micro-political level of pedagogical and applied linguistics, the question is which curriculum, pedagogical approach and what functional language distribution is appropriate and capable of integrating overall cultural and linguistic aims with academic achievement and empowerment in the context of prevailing asymmetric power relations.

In spite of local resistance, most countries officially adopted an intercultural bilingual model in the 1990s that establishes the right to mother tongue literacy and content teaching plus Spanish or Portuguese as a second language for students whose L1 is the indigenous language (Albó, 2002). However, historical discrimination and a pervasive diglossic ideology deeply rooted both in mainstream and in indigenous teachers’ and parents’ attitudes, raise high barriers against the implementation of such a curriculum that would be the most appropriate, both from a pedagogical and psycholinguistic perspective, and from the standpoint of the official declared goals of language maintenance and cultural development (López, 1998; López & Sichra, 2008). The most widespread modality still is transitional “Castilianization” which teaches literacy and content areas in Spanish and makes use of indigenous languages as the initial medium of instruction where necessary. The same procedure applies in Brazil with Portuguese. However, an increasing number of teaching materials in indigenous languages are being used alongside national language primers, and experimental school projects have engaged in new ways of improving indigenous education (Hamel, 2008a).

Immigrant and Elite Bilingual Education (EBE): From Immigrant to Global Language Schools

The history of European and, to a lesser extent, Middle East and Asian immigration to Latin America is well documented. Argentina, Brazil, Chile, Paraguay and Uruguay absorbed about 90% of the European immigration to Latin America (Rosenberg, 2001). During the period of massive immigration (1875 to 1930), Spaniards and Italians represented the largest immigrant group in most countries, followed by the British, Germans, Polish, Yugoslavians (mainly Croatians), and French.

Argentina, Brazil, and Chile received three million Italians and 600,000 Germans (see Bailly & Miguez, 2003). For 1990, high estimates identify some 500,000 speakers and almost 12 million citizens of German descent for Brazil, 300,000 speakers and 1 million descendants for Argentina, and 20,000 speakers out of 200,000 descendants for Chile (Born & Dickgießer, 1989).

Mainly the British-, French-, and German-speaking settlers founded their own schools and other institutions once they arrived to preserve their languages, religion, traditions and endogamic kinship relations. Most of these schools went through four historical phases. Founded as monolingual community or heritage language schools in the 19th or early 20th

century, they provided the children of the settlers with appropriate education, especially in rural areas where no other schooling was available. Teaching was conducted entirely in the immigrant language in most cases, and no students from outside the community were admitted.

In a second phase, teachers were brought over from heritage countries and the national language was introduced almost as a foreign language to provide the necessary language skills in dealing with the external society. Content matters were usually taught entirely in the immigrant language to foster language maintenance.

In their third phase, immigrant schools gradually weakened their character as enclave and ethnic community schools and joined the group of national elite schools (Mejía, 2002), together with other private institutions, opening their doors to the children of the countries' economic and power elites as bilingual schools. Two convergent processes triggered off significant changes in curriculum and language policy. As the immigrant schools became attractive for the national elites, they had to offer a curriculum that could satisfy the educational needs of their new customers. Today, divergent regulations from the home and the host countries often lead to a dual system of parallel curricula with separate languages, faculty, and management which unnecessarily doubles certain content matters taught in both languages. Many schools established segregated tracks for bilinguals and national monolinguals, combining L1 with immersion education.

In a fourth phase, some of the schools associated with prestigious and internationally powerful language communities have developed into "global language schools" (Banfi & Day, 2004) since the 1970s, offering modern, international technology and curriculum together with class segregation and the promise of molding the future leaders of business and politics. Their bi- or trilingual programs and international certificates add a cutting edge to the competitive value of these institutions.

Elite bilingual schools share a model of enrichment bi- or multilingualism (Mejía, 2008). None of the languages involved is under threat or clearly stigmatized, and students are systematically encouraged, awarded and recognized for the bilingualism they develop in the world's "good" languages. The fact that the schools promote bilingualism as a visible and positive trademark in a domain of social prestige has helped to introduce an enrichment perspective and to mitigate Latin American policies of building homogeneous and monolingual nation states.

Common Challenges in Indigenous and Elite Bilingual Education: Integration and Conflicting Orientations

Certainly, the two systems under review have little in common in socioeconomic terms which locate them at the extreme poles between the rich and the poor. Despite fundamental differences, however, a number of sociolinguistic, pedagogical, and curricular phenomena in each system allow for cautious comparison. This entry will focus on problems of integration on various levels: the *internal* integration of curriculum and school communities, the *external* or *national* integration or indeed segregation from the country's political and cultural context, and the *international* integration into a global community of education.

Elite Bilingual Schools

The internal integration of languages, content matters, and teaching methods into a well-structured curriculum challenges many elite bilingual schools. The implementation of two national curricula and separate teaching faculty who frequently know little about the "other" language and curriculum obstruct integrated multilingual communication and academic development.

4 MULTILINGUAL EDUCATION IN LATIN AMERICA

Until now, divergent ideological orientations towards the heritage and the host country may create conflicting asymmetric value systems that affect external or national integration. In addition, many EBE schools maintain little communication with national debates on education. They prefer to connect with their “home” countries and receive academic input, teachers, and teacher training from there.

On the other hand, global integration emerges as a decisive force. In fact, EBE schools in Latin America increasingly incorporate their members into the emerging global arena, creating new de-territorialized “third cultures” and international networks of business, science, and technology.

Indigenous Education

Problems and challenges of integration emerge for indigenous education in Latin America too, though in different ways. Most countries in Latin America possess a national curriculum that engages in a conflicting relationship with the curricular needs and practices of IBE for indigenous populations. Education and language planning for such programs poses problems that can be traced to similar levels of internal, external, or national and international integration.

A number of contradictions arise for the internal integration of the intercultural and the bilingual component of IBE since content matters and competencies from indigenous knowledge base as well as from national programs need to be integrated adequately. To design the appropriate curriculum, indigenous funds of knowledge need to be identified, often reconstructed from oblivion and fragmentation, and systematized to serve as the pedagogical input for the curriculum. The successful integration of such an intercultural curriculum that avoids imbalance, unsuitable misrepresentation of indigenous knowledge via Western systematization, and dichotomized juxtaposition, presents a significant challenge for curriculum design (Gustafson, 2009; Hamel, 2009). As we have seen, the role and the functional integration of the two languages and strategies for their teaching as L1, L2, or as two first languages depending on sociolinguistic conditions posit similar unsolved problems.

The external or national integration of IBE faces similar challenges. To attend the specific local needs, an appropriate IBE curriculum requires a significant degree of independence from the national curriculum which is matter of conflict and negotiation. Some countries like Brazil, Colombia, and Guatemala allow advanced autonomy on the basis of a minimal common core, whereas countries like Mexico and Argentina impose the national curriculum with only slight adaptations (López, 2009). In the end, new programs and practices will only work when they gain legitimacy, that is, when indigenous teachers, students and communities acquire power, a significant degree of autonomy, and control over their education.

International integration of IBE becomes crucial in transnational migration. Many indigenous migrants reinforce their ethnic identity and language use in the host countries in Latin America, the United States, or Europe where they develop lively transnational, often trilingual communities. The educational systems both in Latin America and in the target countries of migration (United States, Canada, European Union) have encountered considerable difficulties and resistance to meet the needs of indigenous migration that has so far remained largely invisible. Education will have to include intercultural components, competencies, and content necessary for survival and empowerment in migration.

Integrating Perspectives from Complementary Knowledge and Experience: Desiderata for Research and Action

Strengths and Weaknesses

In sum, a pluralistic orientation of cultural and linguistic enrichment and intercultural learning could improve internal pedagogical, national (horizontal), and global (vertical) integration.

Indigenous education reveals significant strength in the field of culture and language relations, nurtured by anthropology, descriptive linguistics, and sociolinguistics. The system was for a long time strongly influenced and even administrated by anthropologists, since it was anthropological insight that developed an understanding of how indigenous societies existed and survived as subordinate but distinct ethnolinguistic polities in the context of nation states. Anthropological theory developed frameworks to direct the dynamics of these contacts to enhance either mostly acculturation (Aguirre Beltrán, 1973), or exceptionally independent endoculturation and accommodation without assimilation. Descriptive linguistics provided structural analysis and alphabets, and later on sociolinguistics supplied knowledge about the relations between languages and their speakers, language contact or conflict, shift and maintenance. Clearly, the combined contributions of these disciplines helped to sharpen our understanding of how different cultural models and cosmovisions, as well as asymmetric language conflict relations interfere in the micro-cosmos of the classroom.

EBE in turn has regularly enjoyed significant international investment in modern applied linguistics and foreign/second language teaching, L1 development in contexts of diaspora and language through content teaching. One of its most important contributions is the development of additive enrichment bilingualism, the invaluable experience of creating stimulating environments of bilingual learning that help children to develop self-reliance in their languages and cultures.

On the downside, IBE traditionally had weak input from applied linguistics and pedagogy. The field lacks detailed studies about bilingual language acquisition and academic achievement. Over the past twenty years, IBE has attempted to compensate its deficit in pedagogy, psycho- and applied linguistics by drawing on bilingual education experiences in the United States, Canada, and Europe. In EBE, in turn, there seems to be an acute lack of anthropological and sociolinguistic insight to understand intercultural relations.

Areas of Conceptual Cooperation and Mutual Learning

Indigenous IB schools could greatly profit from L1 development and L2 teaching methodology based on an integrated communicative approach including content and language integrated learning and teaching (CLIL) where EBE tends to be successful. Transfer of cognitively demanding academic skills from one language to the other might improve in both types of bilingual education through exchange and mutual learning.

For elite bilingual schools it would certainly be an enriching experience to introduce an anthropological and sociolinguistic perspective into their work, both on the micro level of their internal integration of languages, cultures, and learning communities, and on the macro level of societal integration. A reassessment of their often dichotomized curriculum, possible conflicts between languages, and their teaching practices from an intercultural learning perspective could help them to reach intercultural competence. Given the drive towards intercultural national curricula for mainstream education in many Latin American countries, EBE could no doubt profit from participation in the debates and experiences in their host countries.

Multilingual Education as a Touchstone for Pluricultural States

A broad comprehensive framework of language policy and planning in applied linguistics is called for to interpret the language and education policies in bi- or multilingual education and to connect all language types involved: the national language(s) of each state, as well as indigenous, immigrant, and foreign languages, both on macro and micro levels. Such a framework understands language policies as a historical process of change in social language constellations where state institutions and other social forces intervene. It encompasses not only the transformation of discursive and linguistic structures and uses (e.g., standardization, *Sprachausbau*, diffusion, shift, revitalization, etc.), but also and fundamentally a change in the relationship that the actors involved establish with their own languages and others in a shared territory as part of overall power relations (see Hamel, 1993, 2008b for a discussion).

When we analyze the language policies concerning the two types of bilingual education and their communities in Latin America, we realize that one common factor which allows for an integrated comparative interpretation is their relationship with the state and the dominant society as it developed over time. Conservative and nationalist forces still consider multilingualism as a problem for the state, although they recognize certain minority rights; and assimilation of minorities is often still the overall goal. Many members of ethnolinguistic minorities have internalized this hegemonic ideology and developed defensive attitudes regarding the “illegitimacy” of their languages. Here, a new language policy needs to be developed to transform the relationship that the dominant *and* the subordinate actors maintain vis-à-vis the prevailing language constellation in order to overcome it.

Bilingual communities and their educational institutions at the two poles of societal stratification may contribute significantly to this transformation in their own ways. In particular, they can demonstrate how the funds of knowledge stemming from their heritage languages and cultures—indigenous or immigrant—make significant contributions and enrich the dominant societies. The undeniable educational leadership of elite bilingual schools in developing enrichment multilingualism can help to erode further the unsustainable ideology of monolingualism. And the unquestionable legitimacy of indigenous claims to be recognized as peoples and to have their linguistic and educational rights respected may work towards the same goal from a different societal pole. Language and education policies promoting diversity for majorities and minorities can no longer be dismissed as marginal components of state policy. They have become a touchstone to appraise the quality of democracy, pluricultural, and plurilingual commitment and the construction of modern states in Latin American and in most parts of the world.

Multilingual Education in North America

ESTER J. DE JONG

Bilingual and multilingual education is one form of schooling that has developed worldwide in response to the linguistic and cultural diversity that characterizes countries all over the world as a result of continuing migration, transmigration, and globalization. Simply defined, bilingual education is instruction that uses two languages as media of instruction. By extension, multilingual education programs are programs whose goals include proficiency in more than two languages. In the North American context, bilingual programs are more common than multilingual education programs.

Some Definitions

“Bilingual students” and “bilingual education” are not synonymous. Bilingual children know and use two languages to different degrees. They demonstrate varying proficiency in their two languages; for example, they may speak both languages but be literate in only one language. Their bilingual skills and the extent they identify culturally with the two languages may develop and vary over time (Romaine, 1995). Bilingual children may or may not attend a bilingual education program.

In this entry, “native language” (L1) will be used to refer to the language in which the child has been raised. In multilingual environments, this can be more than one language and these languages may differ from the (standard) language variety taught in school. The “dominant,” “majority,” or “societal language” is the predominant language used for communication in the students’ nation (including government, education, media, etc). A “second language” (L2) is a language learned at a later stage than the native language. This often occurs outside the home in school. “Heritage language” is the language used by a particular ethnic group. “Minority” or “dominated” languages are languages used by language groups who are politically and socially placed in a minority situation, though they are not necessarily also in the minority numerically. “Majority language speakers” are those who use the societal language.

A final important distinction is that of additive and subtractive learning environments. The distinction was originally introduced by Wallace Lambert, a Canadian psychologist, to explain the positive attainment of French–English bilingual competence in the Canadian context and the struggle of minority-language speakers to achieve the same outcome in other settings, such as the United States. As the two official languages of Canada, both French and English have high prestige. Lambert (1977) refers to this acquisition context as a case of “additive bilingualism” because it involves languages of social value and respect and “the learning of the second language does not portend the slow replacement of it for the home or the other language” (p. 18). In contrast, for speakers whose native languages are not valued there is differential prestige: One language is the high-status language (the societal language), one language (the minority language) is assigned a low status. For these speakers, learning the second language requires them to “put aside their ethnic language for a national language” and their degree of bilingualism will “reflect some stage in the

subtraction of the ethnic language and associated culture, and their replacement with another” (p. 19).

Multilingual competence develops more easily (though not necessarily automatically) in additive contexts since both languages receive attention in schools and in society. In subtractive contexts, multilingual competence will require explicit attention (i.e., time and opportunity) to the overlooked language, the minority language. Specific policies to counter the status differences between the two languages may therefore need to be enacted in schools—for example, through an equal distribution of the two languages across the curriculum, the use of both languages for literacy development. The sociopolitical context (additive/subtractive) is therefore an important variable that affects the maintenance of the proficiency in the minority language when speakers are surrounded by or interact with other languages.

Pathways to Bilingualism and Multilingualism

This entry presents a classification of additive approaches to bilingualism or multilingualism at the primary and secondary level in North America (Canada, the United States, and Mexico). It discusses these approaches in terms of generalized program models that aim for bilingualism and biliteracy and use two or more languages as languages of instruction. This focus excludes foreign language programs for majority language speakers, which only teach the language as a subject. Actual implementation practices may vary from school to school in response to specific school characteristics.

Many different classifications and descriptions of such programs exist (Baker, 2006; Brisk, 2006). The programs discussed here have in common that they aim for the development of bilingual repertoires that include oral as well as written communication (biliteracy). In the United States, these additive bilingual programs are increasingly referred to as “dual language” programs. Their goal of high levels of bilingualism and biliteracy distinguishes them from bilingual programs that may use minority languages merely as a temporary bridge to learning the dominant language. Two additional criteria are useful to distinguish among programs, namely target population and the distribution of the languages. In terms of student population, programs can enroll native speakers of the societal language, native speakers of dominated languages (including indigenous and immigrant languages), or a combination of both target groups. The criterion of language distribution considers how the languages are used for instructional purposes. This includes the amount of time allocated to teach language and the subjects to be taught in each language as well as the choice of the language(s) for initial literacy instruction. Table 1 summarizes the main program models to be discussed in more detail below.

Table 1 Bilingual and multilingual program models

<i>Program label</i>	<i>Language goals</i>	<i>Target population</i>	<i>Language use and distribution</i>
Two-way immersion (TWI)	Bilingualism and biliteracy	Minority and majority	Long-term L1 and L2 use
Canadian immersion programs	Bilingualism and biliteracy	Majority or minority	L2 and then L1 (L1 and then L2)
Maintenance bilingual or heritage language education	Bilingualism and biliteracy	Minority	L1 and L2

Two-Way Dual Language Programs

Two-way immersion (TWI) is an integrated model of bilingual education where native English speakers and native speakers of a minority language are educated together for most or all of the day, and receive content and literacy instruction through both English and the minority language. The model takes advantage of the presence of native speakers of both languages, which allows learners to engage in meaningful communication in both target languages with each other as well as with the teacher (Christian, 1996). According to a national database maintained by the Center for Applied Linguistics (2011), there are currently over 300 TWI programs in the United States. The great majority of TWI programs use Spanish and English as instructional languages (93%), although Arabic, French, Korean, Mandarin, and Portuguese are also used. Further, most TWI programs (79%) are implemented at the elementary (Kindergarten through grade 5) level.

Although different models have been developed, all TWI programs share three essential features:

- TWI programs are considered enrichment programs that aim at three interrelated goals: high levels of bilingualism and biliteracy, grade-level academic achievement, and cross-cultural competence.
- TWI programs enroll approximately equal numbers of native speakers of English and of the minority language, and integrate these two groups of students for most or all of the day.
- All TWI students receive content area instruction and literacy instruction through both languages. (Howard, Sugarman, & Christian, 2003; Howard, Sugarman, Christian, Lindholm-Leary, & Rogers, 2007)

TWI programs are often one strand within a school but can also be a whole-school approach where all students are enrolled in TWI. There are different TWI program designs. Two common models are the 90:10 and 50:50 model. In a 90:10 model, native English-speaking and native Spanish-speaking students are integrated for all subject areas. Spanish is the prevailing language in grades K-3 for all students with 10% of English instruction in K-1, 20% of English instruction in grades 2 and 3. Instruction is balanced between the two languages in grades 4 and above. The students develop their literacy skills in Spanish first and formal English reading is introduced in third grade (Lindholm-Leary, 2001). In a 50:50 model, native English speakers and native Spanish speakers are also integrated for all subject areas at all times. From Kindergarten onwards, they receive half of their instruction in English and half of their instruction in Spanish, often on a week-by-week basis (i.e., one week in Spanish, one week in English). Literacy development takes place in both languages simultaneously. One of the oldest TWI programs in the nation, Oyster Elementary in Washington, DC, implements a 50%-50% model, often with two teachers working together in the same classroom (Freeman, 1998). The K-8 Amigos program in Cambridge, MA, also implements this model, with the addition of Chinese as a third language (Cazabon, Nicoladis, & Lambert, 1998). Both the 90:10 and the 50:50 models integrate students throughout the day.

Canadian Immersion Programs

Probably the best-known bilingual enrichment programs for dominant language speakers are the Canadian immersion programs. Following Brisk (2006), the term “Canadian” is added to distinguish these bilingual programs from (monolingual) English immersion programs

for minority students which aim for second language proficiency rather than bilingualism. French immersion programs were developed in the late 1960s in response to demands from middle-class, Anglophone parents living in predominantly French-speaking Montreal, Quebec, to provide their children with the opportunity to develop a functional level of bilingualism. Immersion programs begin instruction with the least accessible language (the L2) and then introduce the student's native language.

Immersion models differ with regard to the introduction of the second language (early versus late immersion) and the amount of time spent in the second language (full or partial immersion). In early, full immersion programs, the target (second) language, French, is introduced before the student's first language during the first two years of elementary school. By third grade, the student's native language (English) is formally introduced in the curriculum and both languages are used for equal amounts of time for the rest of the program. In the case of late immersion, the second language is introduced either at the upper elementary level (middle immersion) or at the secondary level (late immersion). Immersion programs have been extended to the United States in several different languages including Spanish, French, and Japanese. Programs that initially immerse students in two second languages (e.g., French and Hebrew) before introducing the native language have also been documented (Genesee, 2004; Fortune & Tedick, 2008).

Maintenance Dual Language Programs

Maintenance or developmental bilingual programs teach language, literacy, and content in the minority language as well as the societal language. They include programs for immigrant language and indigenous language speakers. One of the largest districts in the United States, Houston Independent School District, operated several developmental bilingual programs for Spanish-speaking students. Spanish is the main medium of instruction in the early grades with the amount of English gradually increasing until it reaches 50% in fourth grade (Thomas & Collier, 2002). In Rough Rock, Arizona, initial literacy development and content teaching is through Navajo with some time set aside for English oral language development. Subjects are taught in both English and Navajo through second grade. As of third grade, English is used as a medium of instruction and Navajo continues to be used as a vehicle for studying Navajo culture and citizenship (McCarty, 2002). Similar models have been described for indigenous languages in Canada, including Inuktitut and English or French (Patrick, 2005), and for Rarámuri and Spanish and P'urhepecha and Spanish in Mexico (Hamel & Francis, 2006; Paciutto, 2010).

The repression and rejection of the use of indigenous languages in schools as part of nation-building processes has been documented throughout the world. In the United States, the 300 native American languages that existed upon European contact have been reduced to only a small number still widely spoken by children today (McCarty & Zepeda, 1999). As a result, fluent speakers of these indigenous languages have been rapidly disappearing. Similar to the Māori "language nests" in New Zealand, an immersion model has been adopted by indigenous language groups in an effort to reverse these historical patterns of language shift and language loss. Students are initially fully immersed in the indigenous language with the majority language only gradually added as a subject and then as a medium of instruction in the upper elementary and secondary schools. Hawaii has developed a pre-K-12 program in Hawaiian and English (Warner, 2001; Wilson & Kamana, 2011).

Another avenue for supporting heritage language development is the community-based language school. Even though these programs take place outside the confines of formal schooling, they provide access to instruction in the students' native languages and cultures as well as content (e.g., math), mostly through Saturday or weekend schools. This kind of

school has long accompanied the settlement of new immigrants in North America (Fishman, 1980) and currently are organized by many different language groups, including Arabic, Chinese, Khmer, and Korean (Peyton, Ranard, & McGinnis, 2001; Cho, Shin, & Krashen, 2004). In addition to teaching the minority language and culture, heritage language schools also play an important role in helping parents and children negotiate English-medium content taught in the “regular” school and unfamiliar formal schooling practices.

After many years of repression, bilingual program development for indigenous populations in Canada and the United States are now formally acknowledged as an integral part of the right to self-determination of the First Nations People. The situation is markedly different for immigrant languages. In the United States about 50% of the states have passed English-only policies and federal accountability guidelines undermine the implementation of dual language programs. As a result, bilingual development is increasingly supported through less comprehensive though important programs, including a growing number of heritage language classes and community-based language programs.

Alternative Pathways and Possibilities

Formal additive bilingual and multilingual program models are not always feasible, sometimes due to ideological stances, sometimes due to a lack of resources. In other cases, the student population is so diverse that it is impossible to cluster a sufficient number of students to establish a dual language program. In these contexts, the question of how educators can support access to and students’ development of multilingual repertoires is still, and arguably even more, relevant, particularly for minority language speakers, not only because the lived realities of these students are multilingual and effective instruction takes these linguistic and cultural experiences into consideration, but also because of the documented benefits of bilingualism for cognitive and academic development (Cummins, 2001).

Heritage language classes are an important example of efforts to develop bilingual repertoires for minority students. As they teach the minority languages as a subject, they fall outside our definition of dual language education maintained in this entry. However, they constitute an important and growing trend to provide continuing opportunities for language maintenance for heritage language speakers. By the time they enter secondary schools, this group demonstrates a wide range of abilities in the minority language, ranging from receptive skills, to primarily oral abilities, to formal oracy and literacy skills (Valdés, 2005). Although these students are misplaced in a general foreign language class, heritage language class offerings are still limited as part of the regular secondary school curriculum. It is estimated that about 7% of schools offer Spanish for Spanish speaker classes in the United States (Roca & Colombi, 2003; Valdés, Fishman, Chavez, & William, 2006). Some districts have formally linked heritage language classes with college preparatory advance placement (AP) classes or the International Baccalaureate (IB) program in an effort to legitimize these programs and offer more options for bilingual learners.

In multilingual contexts, bilingual programs are generally not feasible due to the presence of multiple languages and too few speakers of each language to be able to establish a bilingual cluster. While it is easily to consider multilingual practices infeasible in such contexts, teachers can still use a wide range of *bilingual teaching strategies* to make instruction more comprehensible, engage students in cognitively challenging materials, and legitimize students’ native languages as resources for learning. Jim Cummins and colleagues describe a multilingual literacies project implemented by monolingual English-speaking teachers working in linguistically and culturally diverse English-medium schools in Toronto, Canada (Cummins, Campoy, Ada, Winsler, & Bleiker, 2006). The teachers invite

their students to write about topics that are aligned with the regular content-area instruction, but written in English and their heritage language. Teachers organize students into same language groups (e.g., bilingual Urdu/English speakers in one group, bilingual Bengali/English speakers in another group), and students draw on each others' diverse language and literacy strengths in English and their heritage language to write their books in two languages. Students publish their dual language books in hard copy and on the web, which develops a multilingual library of student-made books for the school, facilitates students' development of computer literacies, and allows the books to reach a wider audience. Students also participate in multilingual language and literacy surveys, and multilingual math activities (Schechter & Cummins, 2003). Other strategies that bilingual and monolingual teachers can use to make multilingualism a norm in the classroom include providing access to multilingual classroom and school libraries and using multilingual signs and labels and bilingual books for instruction (Ernst-Slavit & Mulhern, 2003). These structured multilingual teaching strategies reflect educators' attitude that it is not sufficient to merely tolerate the presence of the students' native languages. They constantly and purposefully seek opportunities to make multilingualism visible in the curriculum and in the school and extend children's multilingual repertoires, even in the absence of a bilingual program.

Concluding Remarks

The approaches discussed in this entry are commonly distinguished models to support bilingual or multilingual development. It is important to keep in mind that these are generalizations. Schools adopt and adapt these models to their local context to meet their specific linguistic, sociocultural, and sociopolitical needs. Further, bilingual and multilingual approaches to education have to respond to increasingly diverse student populations. The linguistic repertoires developed in these programs need to be more versatile in a globalized world. Expanding our view of bilingual and multilingual education to include opportunities both in and outside regular schooling practices is one way to respond to demographic and social changes. Encouraging schools to examine how they can support multilingualism in multilingual settings is another way. As the pressures of homogenization interact with the need to diversify (McCarty, 2003), allowing different alternative pathways to the development of multilingual repertoires for language minority and language majority speakers will become an important task for language communities.

Multilingual Education in the Arab World

MOHA ENNAJI

Introduction

This entry deals with aspects of multilingual education in the Arab world in general from the historical and sociolinguistic points of view. The focus will be on the Maghreb, particularly Morocco. The following discussion will showcase the similarities and differences between Morocco and other Arab countries.

The Arab world was colonized by different European powers in the 19th and 20th centuries. More precisely, the Maghreb countries (Algeria, Morocco, Tunisia, and Mauritania), Lebanon, and Syria were colonized by France, whereas Egypt, Iraq, Jordan, Kuwait, Sudan, Yemen, and the United Arab Emirates were colonized by Britain, and Libya by Italy. After achieving independence from these Western powers in the 1950s and the 1960s, various changes occurred on the linguistic and cultural levels, namely the ethnic revival and the revitalization of the Arabic language and Islamic culture.

Linguistic Background

The Arab world is characterized by multilingualism in the sense that many languages and varieties are used in different domains, namely Classical Arabic, Standard Arabic, the regional varieties of spoken Arabic, Kurdish, Berber, Nubian, English, French, Spanish, and Italian. The sociolinguistic situation in the Arab world differs from one country to another depending on (a) the different varieties of spoken Arabic in use, (b) the different colonial languages adopted, and (c) the existing indigenous ethnic groups. The multilingual dimension of the Arab world has a direct impact on ethnicity and cultural life in this region of the world and brings about sociocultural problems that must not be overlooked in language planning and in education.

The most salient sociolinguistic feature of the Arab world is the phenomenon of *diglossia* (Bassiouny, 2009, Chapter 1). It specifies briefly that in the Arab world there are two major varieties of Arabic, a high variety (Classical Arabic) and a low one (colloquial Arabic). Other researchers think that today there are at least three varieties of Arabic (triglossia): Classical and Standard Arabic, which are high and intermediate, respectively, and colloquial Arabic (the low variety) (Ennaji, 1991; Youssi, 1995).

Like Classical Arabic, Standard Arabic is a written Arabic variety which has no native speakers. Classical and Standard Arabic are both learned at school only, as they are not spoken languages. Standard Arabic, which is structurally less rigid than Classical Arabic, is both codified and standardized; the policy of Arabization has led to its modernization and to its use as a vehicle of modern culture. It is widely made use of in education, administration, and the media. The expansion of free education has led to the spread of Standard Arabic and to favorable attitudes toward it (see Ennaji, 2005, Chapter 10).

Colloquial Arabic is a major mother tongue which, unlike Classical and Standard Arabic, is unwritten but spoken. Colloquial Arabic can be divided into several regional varieties

2 MULTILINGUAL EDUCATION IN THE ARAB WORLD

(Iraqi, Syrian, Egyptian, Sudanese, Algerian, etc.), which are often mutually intelligible unless they are geographically distant from each other. For instance, Moroccan and Iraqi Arabic are hardly mutually intelligible because they are so remote from each other, and in order to ensure communication speakers of both dialects resort to Standard Arabic.

The other major mother tongues spoken in the region are Kurdish in Iraq, Nubian in Egypt and the Sudan, and Berber in the Maghreb. Kurdish is spoken by about 20% of Iraqis and 15% of Syrians; Nubian is spoken by nearly 5% in Egypt and 10% in the Sudan; and Berber is spoken by 50% of Moroccans and by 25% of Algerians. However, these mother tongues are looked upon by many Arabophones as debased essentially because they are non-standardized, have no religious connotations, and no great written literary tradition (Haeri, 2003, pp. xvi, 184).

Concerning the foreign languages in use, it is worth mentioning English, French, Spanish, and Italian. English is made use of as a second language in the Middle Eastern Arab countries that were previously colonized by Britain. It is widespread in education, scientific research, international trade, and diplomacy and is gaining ground in the fields of mass media, tourism, and finance. English is taught as a foreign language in elementary schools, high schools, and universities. Many Arabs learn English for instrumental reasons in order to have access to modern technology, apply for studies abroad, or communicate with English-speaking visitors and business people. It is spoken widely in the tourism industries by tourist guides, and hotel receptionists (Sadiqi, 1991). English serves the national goals for communicating with the English-speaking world, chiefly the United Kingdom, the Commonwealth countries, and the United States.

In the Maghreb, English has the status of a foreign language; it is widely taught in high schools and universities. It is indeed the most popular foreign language in the Maghreb because it has no colonial overtones in the region (Ennaji, 2005).

French, on the other hand, is widely used as a second language in the Maghreb and in Lebanon. Despite it being a colonial language, it is still prestigious particularly in Morocco, Algeria, Tunisia, and Lebanon. Its chief domains of use are education, administration, government, media, and the private sector. It is employed to achieve efficiency, wider communication, and socioeconomic development.

Spanish and Italian are made use of to a lesser extent in Morocco and Libya, respectively. Spanish is popular especially in Northern and Southern Morocco. Both languages are optionally taught as foreign languages in these two countries.

Arabization

The process of Arabization was meant to modernize and standardize the language in order to meet the needs of the modern Arab states. It also aimed to replace English and French in many fields, particularly in education and mass media. Given the connection between Standard Arabic, Islam, and national identity, Arabization may be considered as a revival of the Arabic language and ethnicity in the societies concerned.

Many minority language activists in the region claim that one purpose of the policy of Arabization is the assimilation of minority groups (cf. Boukous, 1997). However, this is debatable, for the loss of minority languages may be an outcome of Arabization but not its main target. The target is rather religious (Arabic as the language of Islam) and political (a way to unite Muslim and Christian Arabs on secular grounds).

The indirect result of this Arabization policy is the decline of colloquial Arabic, Berber, Nubian, and Kurdish which are not given even the status of regional languages. In the Maghreb, policy makers did not take into account the great number of Berbers (45% of the population in Morocco, 25% of the Algerian population, and 1% of the Tunisian population). Because of this unnatural situation, Berber cultural demands have increased

with the aim of doing justice to the Berber language and culture.

Despite four decades of Arabization in the Maghreb, French is still widely used in education, administration, and the private sector. The efforts of Arabizing the educational system have not fully succeeded for three main reasons: (a) the place of French is still very strong in key socioeconomic factors; (b) the ruling elite holds negative attitudes toward Arabization and the way it has been politicized and implemented; and (c) the official language policy has been inconsistent, and as a result there seems to be no plan to Arabize higher education.

Arabization has had negative consequences on the Kurdish and Berber languages because it has led to their marginalization and to the assimilation of the Kurdish and Berber cultures and peoples. However, in 2001 the Moroccan government decided to revitalize Berber and introduce it into the educational system.

Berber in Education

The attempts to revitalize Berber are motivated by the fact that Berber is the native language of about a third of the Maghrebian population. This language has been in regression under the influence of French, Standard Arabic, and dialectal Arabic. To alleviate this threat on Berber, Berber has recently been officially recognized as part and parcel of the national cultural identity in both Algeria and Morocco. As a result of this move, the authorities have introduced Berber into primary schools and have increased the number of hours allotted to it on radio programs. Berber has also been introduced on television particularly for news broadcasting. As a consequence of the revival of Berber, the number of Berber cultural movements and associations has multiplied (more than 40 exist in Morocco and more than 100 the world over). On the one hand, their objective is to codify and standardize the Berber language and revitalize its culture and literature, on the other hand, it is to sensitize people and governments to the cultural value of Berber as part of the national legacy. The creation of the Royal Institute of Amazigh Culture (IRCAM) in 2001 in Morocco and of the Haut Commissariat à l'Amazighité in Algeria in 2000 is reminiscent of the governments' endeavors to revive and promote Berber language and culture and to meet the demands of Berber civil society.

Arab and Maghrebian people are generally proud of their mother tongues and national languages. Although attitudes toward the different mother tongues and languages have changed among the people, these attitudes have to a certain extent been ignored by Arab governments and decision makers. For instance, Arabization has succeeded only partially after five decades of independence and struggle for the restoration of Arabic language and culture. The mother tongues, notably colloquial Arabic, Berber, Nubian, and Kurdish, are neither codified nor standardized. In the Maghreb, Classical and Standard Arabic are venerated by the population as they have religious ramifications and symbolize national unity, Arab nationalism, and solidarity. Berber and dialectal Arabic, which are considered as means of communication in informal contexts and transactions, have become symbols of identity and authenticity nationwide and in intergroup relations.

Changes in Education and Language Use

Before the French colonization in Morocco in 1911, an Islamic traditional system of education was prevalent. Koranic and religious schools, namely *medersas* and *zawiyas* (mausoleums), offered an Islamic traditional style of education. For centuries, they taught mainly the Arabic language and the holy Koran; the University of Al-Karaouine at Fes, built in the eighth century, helped students to pursue and deepen their knowledge of Arabic and Islamic studies (see Grandguillaume, 1983, p. 70). Islamic philosophy and

jurisprudence were taught, and religious counsels and public notaries were trained in these institutions.

After the proclamation of independence in 1944, Classical Arabic was again declared the official language and French reverted to being the second language. Since then, French has been used alongside Classical Arabic. The former has been adopted for purposes of modernization and development. In this respect, Al-jabri (1973, p. 45) remarks that the Moroccan elite is in full favor of keeping the essence of the educational system of the French colonization and developing it on the basis of the French model.

Various reforms were adopted during the 1960s, 1970s, and 1980s and then the 2000s to bring a change in the educational system. The reformers of Moroccan education laid emphasis on the Arabic language in the curriculum. Another aim was to unify the educational system. This was done in order to curb the differences in quality and standards. Two different educational systems in Morocco have coexisted since 1911—the Islamic model of instruction at Koranic schools, which concentrates on Islamic studies and Arabic literature and the modern model, adapted from the French type, to serve the needs of modern Morocco. Although only a small percentage of students follow the Islamic model, the government stresses this model's importance as a means of maintaining a sense of national and regional identity (Wagner & Lotfi, 1980).

Today, primary and high schools have been totally Arabized: Standard Arabic is the language of instruction for both literary and scientific subjects. In high schools, however, technical studies such as economics, mechanics, computing, and accounting are taught in French. At the university level, the basic language of instruction is French, especially for economics, management, science, and technology.

When children are enrolled in secondary schools (grade 10), they must learn one or more foreign languages, including Classical Arabic, in addition to their mother tongue: Berber or Moroccan Arabic. This language barrier causes some children not to attend school. Parents who can afford it usually enroll their children in private schools where Classical Arabic, French, English, and Spanish are taught, with English being particularly popular (Clark, 2006). A high percentage of these private-school graduates are admitted to universities.

As a *lingua franca*, Moroccan Arabic has become a deep-rooted code in the mentalities of many Berberophones. Through it, the latter sometimes express their beliefs and feelings. Moroccan Arabic is used by both Arabophones and Berberophones as a means of expression of affective and cognitive experiences.

Even though foreign languages are still utilized as means of development and modernization they have become less prestigious than a generation ago, especially French. In Morocco, for example, French has started to slowly give way to English (cf. Sadiqi, 1991). This is due to two main reasons: first, people see French as the language of the colonizer and second, English is the first international language. At any rate, these European languages are not as predominant as in the 1960s in education and administration. Nevertheless, Standard Arabic–French bilingualism is enhanced to achieve efficiency and international communication (see Hargreaves, 1994). Furthermore, most scholars support bilingualism or mastery of foreign languages in addition to Arabic. The eminent Moroccan lexicographer, Lakhdar Ghazal (ex-director of the Institute of Arabization in Rabat, Morocco), argues that if Arabization is a duty, Arabic–French bilingualism is a necessity as far as it serves the enrichment of Standard Arabic.

Language and education in the Arab world must be understood in connection with the broad cultural, economic, and political factors that shape them. The geography and history have largely determined the language planning and education policy in this region. Although Arab countries share common identity formation features—Islam as the main religion and Arabic as a common language—they differ in ethnicity, tradition, history,

and spoken dialects of Arabic. Economic development strategies also vary between the oil-producing states such as Kuwait and United Arab Emirates and the non-oil producing countries such as Morocco, Tunisia, and Jordan.

As a result of government investment in education, the average of educational attainment of the labor force has increased. High literacy rates, regarded as a symbol of national achievement as well as a financial goal, more than doubled in the countries of the Middle East and the Maghreb in the period spanning 1960 to 1995. Morocco is keenly aware of the critical value of education to national socioeconomic development. In 2000, 50% of the Moroccan people were illiterate. According to the 2004 census, this percentage dropped to 40%, but illiteracy is higher among rural women. Despite the improvement of literacy levels in the region, there was a discrepancy between the countries with a significant urban population in which literacy rates had marked a steady increase and the predominantly rural countries where the percentage of illiteracy was remarkably high. Further attempts at raising literacy rates are being processed in the region with a particular emphasis on educating women in rural areas.

Conclusion

To conclude, the multilingual context in the Arab world differs from country to country depending on the Arabic varieties used, the colonial languages adopted, and the existing native groups and minorities. This sociolinguistic situation has important ramifications for ethnicity and politics in the region and gives rise to sociocultural issues that must be taken into consideration in language planning and in education.

Language and education in the Arab world are intimately related. Education, specifically Arabization has led to a change in popular and scholarly thinking. It has brought about the rise of Arabo-Islamic culture and the rejection of a Western lifestyle. This is reflected in the growing emergence of Islamic fundamentalism and thought.

Sociolinguistically, education has affected the use of the mother tongues, Classical and Standard Arabic, and the foreign languages. The mother tongues, namely colloquial Arabic, Berber, Nubian, and Kurdish, are now considered as symbols of ethnic identity, intergroup relations, and cultural authenticity, as they reflect the typical cultural aspects of the region. Attempts are being made by scholars and cultural associations to codify, standardize, and promote these mother tongues to the level of recognized regional languages.

The Arabization policy has contributed to the strengthening of the positions of Classical and Standard Arabic and to the increase of Arab nationalism and ethnic identity. Standard Arabic has been modernized to the extent that it can be used all over the Arab world as a language of wider communication capable of meeting the needs of the modern Arab states and societies.

Language planning in the Arab world ought to be reconsidered taking into account the multilingual context and language attitudes in the region. An adequate policy must seek to further develop and spread Standard Arabic, promote the mother tongues to the level of regional or national languages, and enhance the teaching of foreign languages like English, French, Spanish, and German. This kind of language planning can preserve cultural identity and contribute to establishing efficiency, modernity, and international communication.

Multilingual Identities and Multilingual Education

ANGELA CREESE

Introduction

Identity is a topic of considerable interest in the field of applied linguistics. Research on multilingual identities in multilingual educational contexts investigates the various linguistic resources which multilingual pupils, teachers, and parents use to negotiate selves in classrooms and school contexts. It also explores the kinds of relationships between language and identity that are embedded in both discourses and practices. How schools as social institutions and structures impose identity positions on bilingual and multilingual young people, parents, and teachers is of additional interest in the study of multilingual identities. This entry will review research which explicates our understanding of multilingual identities in multilingual education.

We might think of “best practice” multilingual education as consisting of an ideological context in which educators “fill up implementational spaces with multilingual educational practices” which, as Hornberger points out, often happens in the face of restrictive policies (Hornberger, 2005, p. 606). García, Skutnabb-Kangas, and Torres-Guzman (2006, p. 14) refer to multilingual schools which “exert educational effort that takes into account and builds further on the diversity of languages and literacy practices that children and youth bring to school.” This means going beyond acceptance or tolerance of children’s languages, to “cultivation” of languages through their use for teaching and learning. García (2009, p. 6) argues that what distinguishes bilingual education programs is the goal of using two languages “to educate generally, meaningfully, equitably, and for tolerance and appreciation of diversity.” She points out these programs help students to become global and responsible citizens, and teach them to look across cultures and worlds, beyond cultural borders. Furthermore, they “make schooling meaningful and comprehensible for the millions of children whose home languages are different from the dominant language of school and society” (p. 7). García (2009, p. 8) argues that there is a pedagogic need for “practices firmly rooted in the multilingual and multimodal language and literacy practices of children in schools of the twenty-first century.” Both Hornberger and García offer us an inspirational and aspirational model of multilingual schools. However, we also know that for many bilingual and multilingual pupils, parents, and practitioners this orientation is not what they experience in practice (Blackledge, 2000, 2005; Menken, 2008).

This entry therefore considers multilingual identities in a range of educational contexts and will cover four areas. The first summarizes research which highlights the role of negotiation in identity performance. The second section summarizes research which shows how institutional and social structures shape identity performance. A third section looks at language education and identity. A fourth section investigates identity, language, and cultural heritage in schooling. A final section makes some concluding remarks.

Negotiation and Identity Performance in Schools

Holland, Skinner, Lachicotte, and Cain (1998, p. iv) argue that “Identities—if they are alive, if they are being lived—are unfinished and in process.” In other words, we are always in the business of becoming. Holland et al. describe agency as the process of performing unfolding and shifting identities through socially constructed discourse. They argue for a focus on the micro contexts and the interactions which occur in them as a way of revealing human agency. They suggest this “may be frail, especially among those with little power, but it happens daily and mundanely, and it deserves our attention” (1998, p. iv). Maybin (2006) has shown the importance of looking at identities of young people in schools. Maybin views identity as “dialectically negotiated between young people’s internal definitions of self and other external definitions which are circulated in the social arena through naming and categorizing” (2006, p. 26). Drawing on Jenkins, Maybin shows how young people negotiate and manage their own positioning in relation to their peers and emphasizes the social aspect of identity performance. Indeed, Jenkins argues,

All human identities are in some sense—and usually in a stronger rather than a weaker sense—*social* identities. It cannot be otherwise, if only because identities are about meaning, and meaning is not an essential property of words and things. Meanings are always the outcome of agreement or disagreement, always a matter of convention and innovation, always to some extent shared, always to some extent *negotiable*. (Jenkins, 1996, p. 3; emphasis added)

An emphasis on the negotiation of identities points to the importance of nonstatic descriptive categories and the importance of fluid identities. Pennycook (2003, p. 513) has noted that sociolinguistics has traditionally operated with “fixed and static categories of class, gender and identity membership as if these were transparent givens onto which language can be mapped.” Pennycook points to the need for “far more fluid ways of thinking about language, identity and belonging” (2003, p. 514). Critically, then, any focus on language performance “needs to be understood in ways that do not start with prior social definitions of who we are” (Pennycook, 2003, p. 514). Indeed, it is now well established in contemporary sociolinguistics (Harris, 2006; Rampton, 2006) that one “language” does not straightforwardly index one subject position, and that speakers use linguistic resources in complex ways to perform a range of identity positions, sometimes simultaneously.

Pavlenko and Blackledge (2004) have looked at how identities are negotiated in multilingual contexts. They suggest that five principles must be followed in order to describe multilingual identity. First, that identity options are viewed as constructed, validated, and performed through discourses and that these discourses are available to individuals at particular times and places. Second, that languages and identities are embedded within local and global relations of power which may be challenged, or negotiated, or may be found to be non-negotiable. Third, that identities are constructed at the interface between age, race, class, ethnicity, gender, generation, sexual orientation, location, and social status, and are often fragmented, hybrid, decentered, multiple, and shifting. Fourth, that imagination plays a crucial role in the process of the creation of new identity options. And, fifth, that individual narratives are important in the negotiation and constitution of identities. These principles serve as a useful heuristic in researching multilingual identities in multilingual schools.

Institutional and Social Structure: Shaping Identity Performance

Although the performance of our identities signposts particular subjectivities and shows us as active, creative individuals able to construct social meanings, social structures also

position us in the social world. In other words we are not always at liberty to negotiate identity positions of our choice. Sometimes identity positions are imposed and assigned (Pavlenko & Blackledge, 2004; Wortham, 2006). Identities are also contested.

The study of identity is rich and research in this area documents important studies in a wide variety of different contexts. In a short entry such as this, it is not possible to provide an account of this large literature in any detail. Below, some examples of research are summarized to give the reader a flavor of these studies. One study of how a multilingual educational context imposes stigmatizing identity positions is Talmy's 2004 study of young people learning English in a Hawaiian high school. Talmy demonstrates that hierarchies of English-language learners exist in classrooms and that categories around language learning are culturally produced and reproduced. Talmy refers to the discursive construction of the newly arrived, "fresh-off-the-boat" student, relationally defined against an unmarked, idealized, "native" speaker. Talmy refers to the "linguicism" at work in the social practice of "the public teasing and humbling of lower L2 English proficient students by their more proficient classmates," which "was one of the primary ways that students produced and reproduced the linguist hierarchy" (2004, p. 164). Talmy (2004) argues that such discourses contribute to the reproduction of a form of linguicism which is officially sanctioned, and institutionally situated. Talmy's work points to how institutionalized labels and categories work against the young people they are expected to support.

Another study in Canada (Denos, Toohey, Neilson, & Waterstone, 2009) describes how "many children in today's classrooms quickly acquire identities that are seen as problematic" by schools (p. 30). According to Denos et al., once a child has been ranked, named, categorized, and assigned an identity, "teacher attitudes towards the child and their assigned identity become factors in the access the child has to his [school] community and the resources within it" (2009, p. 37). In other words identities, once assumed or assigned, are difficult to change. This is especially dangerous for multilingual young people who can be positioned by schools as "deficient" or lacking in some way in terms of the majority language. Bilingual students can also experience imposed identity categories which crudely link their language(s) to cultures and nations resulting in essentialized and "romanticized" notions of bilingualism (Leung, Harris, & Rampton, 1997; Harris, 2006).

Language Learning, Multilingualism, and Schools

Lo Bianco (2009) points to "toxic forms of absolutism" in describing multilingual identities and shows how the four institutions of state, nation, language, and religion continue to align in the minds of many. Particularly long-term, according to Lo Bianco, is the "enduring nature of identity work in language" (p. 121). He shows how identity is often equated to language and to national cultures (also see Atkinson, 1999; Holiday, 1999; Leung et al., 1997). He argues that we need a new form of language education which avoids existing agendas and which captures the new and emergent identity positions available to young people learning languages in our schools. He argues for a curriculum which develops "critical worldmindedness" (p. 127). This would see the teaching of languages not linked to discrete and bounded nation-states but as cultures penetrating each other (Makoni & Pennycook, 2007).

Byram (1998) reminds us to distinguish between different kinds of schools when discussing multilingual identities and language learning. His greatest criticism is for national education systems which aim to develop "national identity" through the implementation of a national curriculum. Byram argues that this model has as its ambition to transmit the national curriculum and often fails to address the language learning and educational needs of different linguistic and ethnic groups. Byram suggests that such schools often deny "recent immigrant children" (p. 103) an opportunity to be part of the nation because the

national curriculum bars the coverage of other languages and histories, resulting in multilingual identities, cultures, and histories being excluded.

The language learning and identity of students is a key area of research best represented in the seminal work of Norton (Norton Pierce, 1995; Norton, 2000). She argues that social identity is not something that belongs to the individual but something that emerges out of the learner's interaction with the learning context. She formulated the concept of "investment" to replace the traditional concept of "motivation" in order to better capture the complex negotiation between the language learner and the learning context. Moreover, she points out that language learners do not live in idealized, homogeneous communities but in complex, heterogeneous ones, and that identity construction must be understood in terms of issues of power from within this heterogeneity. For Norton, an "investment" in the target language is also an investment in a learner's own social identity. Van Lier (2008) describes the need to consider the development of new languages alongside the development of existing languages. He stresses the importance of the interrelationship between teacher and learners in making this connection salient. According to van Lier, the teacher engages the learner in pedagogic actions which should develop "a wide panoramic view of self." From this teacher-learner engagement, new identity positions associated with language-learning processes can emerge with the teacher showing the learner the possibilities of these.

Teacher identity and language learning has been discussed by Conteh (2007a, 2007b). She looked at the identity work which bilingual teachers do in primary schools and found that the bilingual teachers used code switching as an important resource to perform their professional identity. This was important to the bilingual teachers as it allowed them to draw on funds of knowledge which they used as "cultural bridging between life in Bradford and Pakistan" (Conteh, 2007a, p. 196). Conteh draws on Cummins (2001, pp. 1–2) to remind us of the potential transformative power of the conversations between teachers and learners. Specifically she argues that code switching "is a distinctive feature of being bilingual, which very clearly links social, cultural and linguistic factors" (2007b, p. 466), and she suggests that this is a particularly important resource in working with second- and third-generation ethnic-minority children from different heritage backgrounds. Creese and Blackledge (2010) found a similar phenomenon in community-run language schools. They describe how bilingual teachers use translanguaging to move between languages to include different participants—students, parents, and teachers—in the teaching and learning of community languages. They argue that this endorsement of flexible bilingualism by the bilingual teachers offers the students an identity position of code switching as usual, acceptable, and positive.

Multilingual Identity and Heritage

May (2001, 2005, p. 330) argues that "historically associated languages continue often to hold considerable purchase for members of particular cultural or ethnic groups in their identity claims." For example Caldas-Coulthard and Fernandes Alves (2008, p. 124) speak of the perceptions of exiled people (or expatriates, refugees, or émigrés) as very much still being "grounded in the concept of nationalism which depends on 'a discourse which still depends on notions of space, of territory'" (Van der Veer, 1994, in Caldas-Coulthard & Fernandes Alves, 2008, p. 124). She shows how the idea of "belonging" to a nation is highly elaborated through symbols and rituals from the mother country.

Educational provision for regional-minority groups has also addressed the study of identity. Cenoz (2009) speaks of the importance of minority languages in education and describes an effort to protect and develop them. Illustrating through the example of Basque educational research, she shows how bilingual education is necessary for the survival and

revitalization of Basque as a minority language. Cenoz reports on work which shows Basque language and culture as important for Basque identity. One government report gives the most important condition of Basqueness as “living and working in the Basque Country” (p. 175).

In the context of research on “heritage-language” education, it is almost a truism that learning the “heritage” language “plays a critical role in the process of children’s identity formation” (Nicholls, 2005, p. 164). Blackledge and Creese (2010) found that a “language” held powerful connotations in terms of a sense of belonging and selfhood in their case study of Bengali complementary schools. Teachers believed that teaching language and heritage was a means of reproducing “Bengali” or “Bangladeshi” identity in the next generation. Classroom interactions became sites where students occupied identity positions which were sometimes at odds with those imposed by the institutions. This research showed young people discursively negotiating paths for themselves which were in some ways contrary to the ideologies of the complementary schools. Whereas teachers and administrators held the view that young people ought to learn Bengali because to do so carried with it knowledge of Bangladeshi history, nationalism, and identity, the young people’s attitudes to their languages, and their multilingual practices, constituted a response to their place in the world, as they negotiated identity positions which took them on a path through language ideological worlds constructed by others.

Creese, Bhatt, Bhojani, and Martin (2006) explored institutionally endorsed identity positions in two Gujarati community-language schools. They found several different identity positions encouraged by the schools. One of these linked language to ethnicity and national culture. Here the endeavor of learning Gujarati was used to remind students of cultural heritages. A second identity position encouraged in the school was a more fluid position which saw the school providing a context for young people to question ethnic, cultural, and heritage boundaries, labels, and categories. Related to this flexible identity position was the use of code switching in the performance of identity. This saw schools institutionally sanctioning the movement between languages in the performance of a multilingual identity which did not tie one language to one culture or heritage.

Conclusion

A view of identity as agentive but also reproduced in social structures has been described in this entry. There are dangers in overemphasizing one over the other. An overemphasis on “agency” and the individual’s ongoing project of identity negotiation could too easily depoliticize important arguments which have revealed continuing unequal relations of power across certain ethnic groups, gender, and social classes. Similarly, an overemphasis on social structures perpetuates the use of crude categories which trap and essentialize individuals. This threat is particularly prominent for multilingual people who find themselves too easily defined around static definitions of culture, nation, and language.

This entry has reviewed research which shows the dangers of using slots and categories which negatively position the “vibrant and multifaceted” multilingual young people in our schools in ways which have harmful consequences for them (Denos et al., 2009, p. 47). Rather than use the old, established categories, we need to develop new ones. This requires looking at current practices to develop pedagogies which respond to and reflect the life experiences of multilingual people (Hornberger, 2008; Creese & Blackledge, 2010). As Denos et al. (2009, p. 47) suggest, we must continue to “actively challenge and resist the question of *difference* with *problem*.”

Through the study of language use in situated practice we are able to understand how people see themselves and perform their social identities. In the study of multilingual identities we are required to look at how the local is embedded in the national. This requires

understanding how local practices engage and connect with diasporic global influences. The concept of “negotiation” of identity emphasizes the agency of the speaker as consisting of many “selves” which shift depending on context. The multilingual individual negotiates with a variety of languages and dialects and these serve as resources in the ongoing business of becoming. At times these linguistic resources are used by the individual to align to larger social categories, such as national, cultural, ethnic, gendered, and class categories. At other times, the multilingual individual resists such alignments and refuses to be essentialized into the social categories being imposed. Multilingual identities are shaped by multiple linguistic and cultural resources, including those associated with heritage languages and those associated with peers, school, neighborhoods, city and rural life as well as with a digital and globalized world.

Multilingualism

JASONE CENOZ

Introduction

One of the earliest references to multilingualism can be found in the book of Genesis, where people who spoke only one language had tried to build a tower “whose top may reach unto heaven” and, in order to prevent this, God made them use different languages: “Go to, let us go down, and there confound their language, that they may not understand one another’s speech” (Gen. 11:1–10, King James Version). In this passage, linguistic diversity is seen as a problem that prevents people from achieving their task—the building of the tower. As Lüdi and Py (2009, p. 155) point out, the idea is that “monolingualism represents an original state, intended by God and/or politically legitimised by human beings.” This positive vision of monolingualism still has currency today. In fact, speaking the same language is considered by many people as more natural and a better scenario than speaking several languages. An example is the link of the state to only one official language and not to the different languages used by different speakers. According to this “one nation–one language” ideology, the use of one single language gives unity and strength and can be a better ground for achieving different goals. This ideology has been very strong since the 18th century in Europe and has spread to other parts of the world.

On the other hand, multilingual individuals (also called polyglots) have always been admired. One of them was Cardinal Giuseppe Caspar Mezzofanti (1774–1849), who spoke at least 38 languages. Another famous multilingual was John Bowring (1792–1872), an English politician and economist, who was fluent in 100 languages and had a basic understanding in many more. Being able to communicate in other languages has also traditionally been part of the skills of a well-educated person. Being multilingual can provide more opportunities for communication and, in fact, multilingual skills could have avoided the problem of confusion created at the Tower of Babel.

In spite of this, there are still many parents and educators who think that raising children in two or more languages can cause some type of cognitive delay or at least confusion. This deficit view of multilingualism was reinforced by early research into bilingualism, which associated bilingualism with negative cognitive implications. This early research had many methodological problems and nowadays is no longer accepted. More recently, most research studies have associated bilingualism and multilingualism with positive effects in cognition and particularly in some aspects of metalinguistic awareness (see Baker, 2011).

Another issue related to the more or less positive implications of being multilingual is related to the status of the specific languages involved. Some European languages such as English, French, or German have a high status as “foreign languages” and result in so-called “elite multilingualism.” Speaking these languages has always been a marker of high status in opposition to folk or nonelite multilingualism, which involves languages that can be used by minorities, immigrants, or powerless people. This second type of multilingualism is more widespread. In many of these situations schoolchildren who speak languages with a low status in a given society are expected to become monolingual in the high-status language and to assimilate to the dominant culture without getting any

support for their first language. In these contexts negative attitudes toward multilingualism may be found coming not only from monolingual speakers of the high-status language but also from multilingual speakers.

Definition of Multilingualism

The term “multilingualism” is used in different ways. Multilingualism is a complex phenomenon because it is affected by many factors and can take place in a very wide range of situations. One of the first issues to consider is the number of languages involved. Multilingualism clearly refers to more than one language, but the distinction between bilingualism and multilingualism is not clear-cut. The term “bilingualism” means “two languages” (Greek prefix *bi-* = two), but traditionally it has also been applied to more than two languages, which is not etymologically accurate (see, for example, Bloomfield, 1933). The word “multilingualism” means “many languages” (Latin *multus* = many) and is a term applied by some scholars to two languages and by others to three or more languages. For example Kemp (2009, p. 15) considers that “most researchers in language research use the term ‘bilingual’ for users of two languages and ‘multilingual’ for three or more, but this is not universal.” It is difficult to know the relative number of researchers that make this distinction because “multilingualism” is a term that seems to be gaining currency at the expense of “bilingualism” even when only two languages are involved. If we take the etymological origin into consideration, “two languages” does not seem to be “many” (*multi*), but it is arbitrary to decide that the line has to be drawn between two and three languages and not between three and four, for example. In any case, etymology is only one of the criteria to be taken into account and research on the acquisition and use of third and additional languages will probably establish the similarities and differences between the different processes. In this entry we will use the term “multilingualism” in a broad sense, including bilingualism.

Multilingualism may refer to many aspects of life, but one of the basic distinctions is between its individual and social dimensions. Individual multilingualism (also called plurilingualism) refers to the ability that individuals can have to communicate in two or more languages, while societal multilingualism refers to the languages used in a specific society. Obviously, individual multilingualism is closely related to societal multilingualism because if more languages are spoken in a given community it is more likely that the individuals who live there speak more than one language. However, there are multilingual individuals who live in a relatively monolingual society, particularly in the case of elite multilingualism. At the same time, there are contexts of high linguistic diversity such as many of the big cities in Europe or North America with a large percentage of monolinguals. The European Commission combines individual and societal multilingualism in the following definition: “the ability of societies, institutions, groups and individuals to engage, on a regular basis, with more than one language in their day-to-day lives” (European Commission, 2007, p. 6). This definition also considers multilingualism to include bilingualism.

The Scope of Multilingualism

The study of multilingualism has attracted the interest of scholars in different disciplines. These disciplines look at different aspects of multilingualism on individual or societal levels and their research is based on different theoretical approaches and also uses different methodologies. In this section some of the main approaches are summarized.

A perspective based on linguistics focuses on the characteristics of the languages which are analyzed. One of the issues in the study of multilingualism is the linguistic distance

between the languages involved because of its implications for areas such as crosslinguistic influence, receptive multilingualism, or multilingual education. Another area that has received a lot of attention in recent years is early multilingualism. Studies in this area have focused on the simultaneous acquisition of two or three languages by looking at the development of grammar, phonetics, pragmatics, or lexis from a very early age (see De Houwer, 2009). The findings of these studies, which are typically longitudinal and follow the development of bilingual or trilingual competence for months or years, are based on audio and video recordings of oral interaction recorded while the child uses different languages with other speakers. This type of research has provided interesting insights into the different stages of development and the relationship between the languages being acquired.

The way multiple languages are processed by individuals is also of great interest in the study of multilingualism. There are many methods to find out how the brain functions when processing language. The study of aphasic patients can provide valuable information by analyzing the effect of brain damage on specific aspects of language processing. One of the techniques most widely used, both with aphasic and with nonaphasic individuals, is event-related potentials (ERP), which allows researchers to observe brain activity during specific cognitive processes. There are also new advances in neuroimaging that allow the examination of brain activity with more accuracy by using functional magnetic resonance imaging (fMRI) or positron emission tomography (PET). In the case of multilingualism, one of the main issues is the brain mapping of languages, that is, to find out whether different languages are processed in different parts of the brain, but so far the results have not been consistent. There are some methodological problems because of the great diversity of situations in the way multilinguals acquire and use their languages and the different aims and designs of the research studies. Van den Noort, Bosch, and Hugdahl (2006) review some studies and conclude that there are stronger activation patterns in the brain when bilingual speakers are processing their second language.

Other experiments on language processing have focused on the areas such as the organization of the mental lexicon or the differences between monolinguals and multilinguals in metalinguistic awareness. In the case of the multilingual lexicon, it is common to use techniques such as reaction times, semantic priming, and lexical-decision tasks. There has been a lot of interest in analyzing whether there is separation or integration of the operations of the mental lexicon and the main conclusion seems to be that there is a high degree of interplay between the mental lexicons of the different languages (Singleton, 2003). An interesting perspective is the conceptual representations that multilinguals have of the lexicon as compared to monolinguals (see Pavlenko, 2009). This perspective explores the differences between monolinguals and multilinguals in the categorization of objects, events, and actions. Research studies have also related multilingualism to metalinguistic awareness, that is, the ability to reflect on language and look at it objectively, focusing on its structure and functions. According to Bialystok (2001), bilinguals tend to obtain better results in some dimensions of metalinguistic awareness: tasks aimed at identifying words and tasks that demand high levels of control of attention. Bialystok, Craik, Klein, and Viswanathan (2004) also found that lifelong bilingualism could possibly slow down the process of cognitive decline.

A related aspect of multilingualism that has received a lot of attention in the last years is its dynamic character. In contrast to earlier views, nowadays multilingualism is not seen as static and fixed, but more as changing according to the different processes of acquisition and attrition. Herdina and Jessner's *A Dynamic Model of Multilingualism* (2002) explores the psycholinguistic dynamics of multilingualism and shows how the constant interaction between a speaker's multiple languages creates new structures and emergent properties that are not found in monolingual systems.

Another line of research that links linguistic and psycholinguistic perspectives comes from specific studies on crosslinguistic influence in the acquisition of third or additional languages. These studies suggest that there could be closer links between languages other than the first and also between languages that are typologically close (see, e.g., De Angelis, 2007). Apart from linguistic transfer, crosslinguistic influence at the conceptual level has been analyzed as well as the multidirectionality of crosslinguistic influence, its relationship to proficiency, and the influence of factors such as motivation or personality (Jarvis & Pavlenko, 2008).

The study of some affective variables such as attitude and motivation has a long tradition but other aspects of emotions as related to multilingualism have received more attention in recent years. The study of issues such as the way emotions are expressed in different languages, or the emotional experience of acquiring and using different languages, opens new perspectives in research on multilingualism (see Pavlenko, 2005). One of the methodological techniques to analyze emotions and multilingualism is to look at narratives written by multilingual speakers. For example, the following multilingual speaker highlights the role of emotions: “My experiences and subsequent choices highlight the powerful effect of emotions on the enterprise of learning. At least for some personalities—such as mine—the emotional context of learning a language can be a make-or-break issue” (Freedman, 2009, p. 149).

Multilingualism is also examined in sociolinguistic studies. In this case, research on multilingualism has focused on different areas such as language policy and language planning, attitudes toward languages, or the use of different languages in specific contexts (home, with friends, work, media, internet, etc.). Language policy and language planning studies focus on different aspects related to the status, use, and acquisition of different languages. Research on language planning looks at specific interventions aimed at modifying the corpus of a language, its status, and acquisition. For example, the government of a country, region, or agency can decide to create a standard form of a language to be used at school or in the media. It is also possible to establish norms about the use of languages in different domains such as the school curriculum, or the signs in the linguistic landscape. Schools are crucial agencies in language planning because there are important decisions to be made about which languages are studied as subjects or which languages are used as languages of instruction. In many cases, the language schoolchildren use at home is not taught at school. Schools can also contribute to setting different values and ideologies about languages (see, e.g., Heller, 2007). Some of the studies in this area analyze discourse practices involving different languages in school contexts using an ethnographic methodology based on observation and interviews so as to identify these practices as related to ideologies. For example, Blackledge and Creese (2009) distinguish between the ideology of “separate bilingualism” that tries to keep languages apart in separate containers and the ideology of “flexible bilingualism,” when the speaker and not the language is the center and language practices allow for combining different languages.

Even though multilinguals can speak different types of languages, when two languages are spoken in the same community, there are important differences between speakers of majority and minority languages. Speakers of majority languages can usually choose to learn the minority language or not, but speakers of the minority language need to learn the majority language.

According to Harrison (2007), more than 40% of the languages in the world are endangered. Many other languages are not in this situation, but are surrounded by strong languages so their vitality may also be threatened to some degree. Lesser-used languages can provide a sense of identity and, apart from being used for communication, they can have a symbolic value. One of the first measures undertaken to revitalize a minority language is the provision of some form of teaching. This teaching can be extracurricular

or inside the official curriculum, and in some cases a minority language is used as the language of instruction for all levels in education. Research on the acquisition and use of minority languages in contact with other languages can be relevant for areas such as L1 literacy, second language acquisition, bilingualism and multilingualism, language and identity, language policy, and the acquisition of additional languages.

The study of multilingualism in the linguistic landscape offers a different perspective in the study of multilingualism. The linguistic landscape refers to the signs of different types that can be found in different cities. Studies on the linguistic landscape conducted in different settings confirm the spread of multilingualism and are indicators of linguistic diversity in the public space (Shohamy & Gorter, 2009). The multilingual linguistic landscape that can be found in different parts of the world usually includes English as one of its languages. The intensity of the use of English in different domains all over the world is a new phenomenon as compared to other languages of international communication used in the past. Multilingualism with English can be found on the street but also in the school curriculum, at work or on the Internet. English is a very strong language but it is very often used in contact with other languages. For example, English is the most widely used language on the Internet; it is estimated that English was used for 51.3% of the information on the Web in 2000, but only for 27% in 2009 (Graddol, 2006; Internet World Status, 2009). This means that other languages are useful for their speakers in their everyday lives. English is considered a resource which opens doors for better opportunities and it is associated with social and economic mobility. At the same time the spread of English is also felt as a threat.

The study of individual and societal multilingualism focuses on all the topics that have been discussed in this section and many others. In fact multilingualism is related to cognitive and affective dimensions of individuals but also to their social interaction, and has historical, political, social, psychological, economic, and educational dimensions. Multilingualism at the level of the individual and of society has great diversity regarding the structural characteristics, roles, and use of the languages involved, as well as the social or educational contexts, among others. As the number of existing languages is much larger than the number of independent states, individuals and whole communities need to speak more than one language in many cases.

Multilingualism is an umbrella term that covers different processes and situations which are very common in the world. Taking into account its broad scope, a single theory cannot possibly explain its diversity and complexity.

Multilingual Competence

The definition of multilingualism that we have adopted here is that of the European Commission, which refers to the ability “to engage . . . with more than one language.” The term “engage” refers to “being able to communicate,” but it is obvious that communication can happen at different levels, through different channels, and usually results from a combination of different modalities that include languages but also gestures, visuals, and other semiotic systems. One of the concerns of scholars has been to define the level of proficiency needed in two or three languages to be considered multilingual. The idea of “native control of two languages” suggested by Bloomfield (1933) is not very realistic, particularly if a multilingual uses three or more languages. The idea of the native speaker as a reference for language learning is no longer unanimously accepted. Becoming a native speaker of several languages is very exceptional because multilingual speakers are not the sum of several monolinguals. Even the idea of balanced multilingualism with similar levels of proficiency in the different languages is not realistic. Multilinguals do not use all

the languages in their repertoire in the same way for all functions. They choose different languages according to the context, taking into account factors such as the interlocutors, the action, or the setting. They have preferences for some languages to carry out some actions. The emperor Charles V (1500–58) famously said: “I speak Spanish to God, Italian to women, French to men and German to my horse”—this is an example of the preferences of a multilingual speaker. Nowadays multilingual speakers also have different preferences and domains of language use when they choose different languages as they browse the Web, answer the phone at work, read a novel, or chat to a friend. In fact, multilinguals use languages for different purposes according to their own preferences and the communicative needs of their interlocutors, and very often do not use all the languages they know to the same extent in different communicative situations. Cook (2007) sees the need to adopt a multicompetence view that considers multilinguals as the norm and not the exception. Multicompetence is the knowledge of two or more languages in the mind and it is a reaction against the traditional focus of SLA research that used the native speaker of the target language as a reference. The idea is that a multilingual person’s competence cannot be compared to that of native speakers because their minds are different. Knowledge of the L2, L3, or L4 is different, but the process of acquiring these languages has an impact on the first language. Furthermore, multilingual speakers use languages in different ways because they can switch languages; their different languages make them change perceptions and affect their conceptual representation (see also Pavlenko, 2009). Therefore, multilinguals are different from monolinguals and should be seen to possess unique forms of competence, or competencies, in their own right.

Multilingual speakers use languages as a resource in communication. Code switching and code mixing are more common in some contexts than in others. Grosjean (1982) proposed the concept of language mode to refer to the state of activation of the languages spoken by bilinguals depending on the interlocutor, the content of the discourse, the setting, or the function of the interaction. Language mode can be represented as a continuum with two poles. When bilinguals interact with monolinguals, they are toward the monolingual end of the language-mode continuum and only one language is active. When they interact with bilinguals, they are toward the bilingual end of the language-mode continuum and they mix languages more often because both languages are active. Bilinguals can also find themselves in positions between these two poles. Although code switching in real communication is obviously linked to contextual factors, psycholinguistic experiments suggest that the role of the nonlinguistic context is not as important in the activation of the languages in the brain (Dijkstra & Van Hell, 2003). Psycholinguistic experiments show that bilingual speakers activate their languages in parallel and become skilled in negotiating the existing competition among the languages they know so as to use the language (or languages) that is most suitable to the context (Kroll, Bobb, Misra, & Guo, 2008).

Multilingual speakers switch languages to convey their communicative intent and in many cases to achieve a specific communicative effect. Baker (2006) lists 13 possible reasons for code switching that include, among others, when it is difficult to retrieve a word, when the concept does not have an equivalent, or when a special point needs to be emphasized. Code switching is sometimes regarded as a negative practice, particularly in educational contexts, but there is a recent trend called “translanguaging” that uses the alternation of two languages as a pedagogical strategy. Translanguaging can refer to receiving input in one language but producing output in another language (see García, 2008). Another way of switching languages that also distinguishes between productive and receptive skills is “receptive multilingualism.” Speakers of related languages use their respective first languages, which are closely related, and try to understand the languages used by their interlocutors (see Ten Thije & Zeevaert, 2007).

Conclusion

Multilingualism is a very common phenomenon in the world and it is often said that being multilingual is the norm and being monolingual the exception. Estimations about the number of multilinguals in the world are not easy to make, but there is no doubt that a large number of people in the world speak two or more languages. Multilingualism is not a new phenomenon but it has some specific characteristics nowadays, such as the spread of English or the use of different languages in education.

Theoretical and empirical work on multilingualism shows that multilingual individuals have some characteristics due to the existence of two or more languages in their minds and the use of those languages in specific social contexts. After many years of rigid monolingual approaches in the study of different aspects of multilingualism, there is a trend toward considering multilinguals as such and not as speakers or imperfect speakers of each of their languages. This approach, based on the multilingual's whole linguistic repertoire, can open new perspectives for the study of both individual and societal multilingualism.

Multilingualism and Identity

DIEGO PASCUAL Y CABO AND JASON ROTHMAN

Introduction

The term “multilingualism” is most often used to refer to a state of linguistic knowledge, environments, or speakers in relation to which a minimum of three languages are implicated. When we speak of multilingualism in this entry, however, we include the case of bilingualism, following Romaine (1995) and understanding the term “multi” to refer to “more than one.” In the Western world, multilingual scenarios are commonly taken to be exceptional, rare if not mystifying, despite the fact that multilingualism as such actually describes the reality of the majority of individuals and environments across the world, including a multitude of people in countries largely considered monolingual, such as the USA. That multilingualism abounds and is a naturally occurring inevitability is simply observable at the societal and individual level. However, the focus of the present discussion seeks to ponder what multilingualism brings to bear on the construction and performance of identity. This is the task we turn to in the remainder of this entry.

Connecting Language to Identity

Being the mode at our disposal to express our thoughts, desires, emotions, and the like, language is omnipresent. Language is unmistakably linguistic in the formal sense of the word, but it is much more at the same time. Language is one of the most reliable constructs of human society; from the time we are born we are surrounded by it and, since all communities have language, it is virtually synonymous with being human. No one has ever claimed that language exists within a vacuum; even though some linguists are uninterested in the sociological side of language, this does not entail that there is an *a priori* rejection on their part to the intuitive notion that language is obviously a social construct. Putting aside questions related to how language is acquired and mentally represented in a cognitive sense, which are best left to formal linguistics, the extent to which one could possibly fully understand language in the absence of conceiving how it comes to bear on society, and society on it, is limited. The notion of linguistic identity acknowledges the role that language plays in the shaping of personal and societal identities, from construction vis-à-vis linguistic negotiation to identity performance via language use. Those who study linguistic identity understand that language leaves its mark on personal identity as much as individuals leave their mark on the languages they speak (e.g., De Fina, Schiffrin, & Bamberg, 2006). Insofar as this is true, it stands to reason that linguistic identity in multilingualism would entail even more dynamic construction and performance processes that would not—in fact could not—be unvarying or consistent precisely because multilingualism itself is a fluid concept and subject to multifarious differences specific to each instance of contact. Of course, this does not mean that there are not commonalities to be appreciated from bringing together similar or even vastly different cases of multilingualism, but is rather a proviso that one must consider the specific variables that are sure to be unique as they relate to the linguistic identity of multilingual individuals, communities, and nations (e.g., Niño-Murcia & Rothman, 2008).

2 MULTILINGUALISM AND IDENTITY

Research on the concept of identity, as it relates to language and language use, is currently at the forefront of research in the field of sociolinguistics. This type of research has informed and is informed by linguistics, sociology, and anthropology as it contributes to the general knowledge of human behavior. The systematic analysis of social and linguistic data from environments where two or more languages coexist provides us with extremely valuable information regarding its speakers' linguistic behavior (both at the individual and at the collective level). Critical to this form of analysis is the underlying fact that we can better appreciate some of the intricacies that govern multilingual contexts everywhere, that is, we can understand how an individual is self-positioned in such an environment and how she or he constructs social positions among others (e.g., Bucholtz & Hall, 2005).

Questions such as what it means to be Turkish or Swedish are already tricky, if not loaded. Nevertheless, pondering what it might mean to be Turkish-Swedish in Sweden, where your reality might sit between two linguistic codes (Turkish and Swedish) and where you might not feel authentically part of either of the subcultures that contribute to the label, is likely to be more complex. To be a Turkish-Swedish, Japanese-Brazilian, Algerian-Italian, Moroccan-French, or Basque-Spanish individual in no way guarantees that your experiences, linguistic and otherwise, are truly comparable to all members of such groups; however, it might mean that there is in some way a common basis for how your identity comes to be constructed. In this case, living between two cultures, two languages, and the like calls forth separate linguistic identities that are unique from monolingual ones. Novel linguistic codes are born from such experiences most naturally, and often not out of seeming communicative necessity as is the case with typical pidginization and creolization processes. The fact that multilingual speakers can alternate between two or more languages in their speech is a valuable tool to establish in-group and out-group membership. Multilinguals are aware of their linguistic abilities and they know how their speech production differs considerably from monolinguals'. New linguistic codes that reflect the hybridity of identity in multilinguals are abundant and are often indicators of inclusion into and exclusion from multilingual groups. For example, according to Zentella (1997), Spanglish is the code of choice among Nuyoricans (people of Puerto Rican descent in New York) even when they are seemingly equally fluent in Spanish and English. In a way, such individuals are trilingual, employing the languages within their repertoire and combining them in novel yet constrained ways when appropriate, in accord with the social and linguistic prudence that each situation dictates.

In the past, identity was treated as a permanent label and it was therefore assigned to groups of individuals that shared a common set of attributes irrespective of other differences. These individuals were assigned into preexisting and predetermined categories that targeted the collectivity and left aside individual variations. More recently, the concept of identity has been redefined and the focus of attention has shifted from collective and immutable to individual and ever-changing. Therefore, linguistic identity is now seen as a personal trait in constant process of development that is relentlessly being renegotiated according to individual circumstances. In this frame, the focus has shifted from absolute finished values to the value of performativity itself (Austin, 1975; Cameron, 2001, 2005). This concept has consequences for multilingualism too. Relative preferences and affinities for language choice and use at the multilinguals' disposal can and do change, often cyclically, and are related to external and internal influences while at the same time reflecting the fluidity of linguistic identity on a continuum of time.

Construction and Identity in Multilingualism

In a very broad sense, social identity focuses on the contrasts between "I" and "you" and between "us" and "them." It is through the experiences we have with other people that

we derive and develop our own identity and ultimately how we assign societal roles to others and ourselves. In this respect, the general use of language, as it relates to identity, and the specific linguistic choices reproduced in every speech act, are clearly never neutral. Although mostly done subconsciously, individuals continually construct and negotiate their uniqueness to project an image of themselves. While most individuals do so following general social and linguistic patterns, others deviate from them, producing so-called “deviant” identities (Cameron, 1995, p. 16). This is especially true among multilinguals whose linguistic repertoire, as described in the previous sections, allows them to act inventively as a byproduct of different resources they uniquely have. Whether they choose to use only one language, go back and forth indiscriminately between languages, or combine languages in interesting ways, multilinguals make use of their linguistic tools with the motivation, conscious or unconscious, of accomplishing different effects. These effects may range from amiable in-group interactions to hostile rejections toward the out-group. Whatever goal from this continuum is elected, the linguistic act embodies a process of identity (re)negotiation. In this sense, individuals have choices to make that have various consequences. Electing to align with a mainstream society may convey more privileges, while the use of another language, a more stigmatized one in a given society or subpart of a greater society, may be indicative of ethnic pride, or jeopardize social acceptance in some spheres. These kinds of privileges are therefore established, revoked, or maintained via linguistic choices. As such, external stimuli become internal variables that mediate linguistic choices, which are in turn witnessed in identity performances.

Language is, therefore, seen as an essential, distinctive element of a person’s identity whether multilingual or not. It is reasonable, then, to hypothesize that the interplay of multiple linguistic codes within the mind of an individual comes to bear in nontrivial ways on the realization and maintenance of multilingual identity. Nonetheless, the amount of linguistic decisions that an individual has to make is drastically reduced by external factors such as our nationality or ethnicity, a point to which we turn in the following section.

National and Ethnic Identity

Today it is not uncommon to find political and social movements all around the world that call upon language as symbolic and inherently related to the concepts of nation, group, and identity. In the USA, for instance, the current English Only Movement has tried to make official the hegemony of the English language for decades. This debate, however, is not a new one. In fact, this association in contemporary times can be traced back to German Romanticists of the late 18th and early 19th centuries, such as Wilhelm von Humboldt, Johann Gottlieb Fichte, or Johann Gottfried Herder. These philosophers raised fundamental questions regarding the relationship between nation and language, indicating that these two elements are inseparable. An essential component of a nation, they hypothesized, is its language. Because we all use language and different ethnicities have different codes, language is an obvious and extremely effective vehicle that can be used to unite and divide masses. In modern history, the early and mid-part of the 20th century knew this game all too well as German, Italian, and Spanish were used in Europe as a means of defining inclusion and exclusion.

What does language’s proverbial capital mean in a postmodern era in which the process of globalization surrounds us? Now, more than ever before, people are able to travel great distances in a matter of hours or can communicate effortlessly across the world with the simple touch of a button. In this sense, globalization is forcing the disappearance of our boundaries, physical and linguistic. This globalization comes with a very substantial price tag: homogenization at several levels. At the linguistic level, the one with which we are

concerned here, even if this globalization is favoring the spread of some languages and the disappearance of others, bilingualism (or multilingualism), and not monolingualism, is prevailing all over the world, whether it is officially recognized or not (Romaine, 2010, p. 26). Conversely, although the process of globalization and contact might most commonly meet with linguistic erosion, erosion itself can have the effect of rejuvenating pride in languages and their revitalization, motivating people to unite in an effort to reclaim their linguistic rights (see, e.g., Niño-Murcia, Godenzzi, & Rothman, 2008). This trend is nicely evidenced in the resurgence of regional languages and their co-official status in Spain where they were outlawed during the Franco regime in the mid-20th century.

The concept of ethnicity is seen as a subset of nationalism that gets especially promoted in contexts of intense immigration. In these contexts, the friction that appears between the members of the host community and the newcomers is translated in the creation of the so-called minority groups. At first, linguistic differences promote the boundaries between them. With time, these boundaries tend to disappear due to the partial or total integration of the minority group into the mainstream, a sign that acculturation has taken place. At this moment “ethnicity becomes a symbolic ethnicity” (Gans, 1979). Lack of active participation in linguistic exchanges, therefore, does not completely determine belonging to an in-group. This may have evolved into another type of identity available to an individual: ethnic identity.

Multilingual Education and Identity

It should not be controversial by now to acknowledge the fact that we live in a world in which multilingualism, and not monolingualism, is the norm, yet in many multilingual societies speakers do not always have access to an education that promotes such diversity. In many cases, minority languages are the language of instruction only during the first years of an individual’s education, and they are later replaced by other more prominent languages (Cenoz, 2009). In the context of globalization, the external pressure to acquire such prestigious languages, such as English, can hinder the development of languages with less prestige. This is clearly detrimental and prejudicial since it may result in a gradual language loss in the case of minority/heritage languages. Education seems to be the best weapon against this form of linguistic stagnation. In this sense, the positive outcomes of well-developed educative policies on languages are potentially manifold, as long as they become more inclusive and more receptive of multilingual and multicultural individuals. An effective use of educative policies is therefore one that recognizes the importance of language maintenance of the minority language(s) while facilitating the acquisition of other more prestigious languages. While the presence of these policies will not assure language maintenance in any community (Cenoz, 2009, p. 11), in their absence this process will most likely result in language shift toward the majority language.

The case of languages such as Basque and Catalan in Spain is a good example of how educative policies can help recover a weakening linguistic panorama, restoring pride in linguistic identities that include minority languages by officializing their importance from the top down. This nationalist view of “one nation-one language” that dominated the time of the Franco dictatorship resulted in the official barring of the languages. During that time, a strong sense of stigmatization was associated both with these languages and with their speakers. With the turn of the century, social and educative reforms have changed the panorama with the positive effect of revitalizing these languages.

While there are a few agencies that are working to increase awareness on language policies, the number is minimal. Much work is still to be done to foster a larger number of minority languages and encourage the positive view of multilingualism. Multilingual

education not only motivates the acquisition of languages while protecting minority languages, it also legitimizes the existence of minority languages and promotes the sense of pride they should entail in the linguistic identity of its speakers.

Some Concluding Remarks

Whether multilingualism is an individual phenomenon or a societal one has not been clearly defined (Niño-Murcia & Rothman, 2008, p. 21), although we take it to be both. While we are clearly all individuals and function as individuals, we should not forget that we are also social beings and live in a social world. Multilingual communities can be found all around the world in different contexts. Sometimes multiple languages coexist without apparent tension, such as French, German, and Italian in Switzerland or Spanish and Catalan in Andorra. Other times, as is the case in Belgium, one language (Flemish) is relegated to informal in-group activities while another (French) has the public recognition (Myers-Scotton, 2002, p. 35). Other times, more than one language, or varieties of the same language, coexist, but one is predominantly more prestigious than the other; in the case of true diglossia, two languages coexist and are used for different purposes by the same community. Examples of diglossia abound, such as the case of heritage languages in the USA or the case of Arabic in the Middle East (Shiri, 2010). Even though the rewards of multilingualism are well documented (e.g., Coulmas, 1992; Myers-Scotton, 2002), when two or more languages coexist, there is a tendency to shift to the most prestigious language, which may result in language loss. At present, most government agencies are not taking the necessary measures to foster multilingualism. Educative and social reforms are therefore needed across the board in order to address the linguistic needs of the multilingual and multicultural society that we currently live in.

What is clear from this nonexhaustive introduction to the multiple variables inherent in the complex notion of linguistic identity in multilingualism is that the issues at stake are even more polarized, complex, and idiosyncratic in some ways than the same processes in monolingualism. Future research on linguistic identity and multilingualism is welcome and the emerging trend of specific research is sure to be insightful and enlightening on many planes.

Multilingualism and Aphasia

YOUNGMI PARK AND LORAIN OBLER

Over half of the world's population speaks more than one language (Garcia, 2002) and everywhere a percentage of individuals will become aphasic as a result of brain damage, losing previously acquired language abilities to a greater or lesser extent in various patterns, linked to which regions of the brain are damaged. Interesting questions have been asked about such individuals concerning how their aphasia manifests itself in each language, what the explanations are for patterns of differential recovery, how multilinguals' aphasia should be treated, and what multilinguals' aphasia phenomena tell us about language organization in the brain more generally.

Patterns of Aphasia in Multilinguals

When bilinguals or multilinguals develop aphasia, their languages are most often affected equally, in proportion to how well they were known before the aphasia-producing incident. Sometimes, however, they are impaired selectively (Paradis, 1977) and, rarely, languages are impaired differently in terms of quality (e.g., one language with fluent aphasia, the other language with non-fluent aphasia) and in terms of quantity (e.g., mild deficits in one language, severe deficits in the other language). According to Paradis (1977), there are six types of recovery patterns from bilingual or multilingual aphasia: parallel, selective, successive, differential, antagonistic, and mixed.

Parallel recovery occurs when two languages recover simultaneously and to the same degree. This recovery pattern is the most commonly found in bilingual aphasics (Albert & Obler, 1978; Karanth, Ahuja, Nagaraj, Pandit, & Shivashankar, 1991; Fabbro, 2001). Selective recovery occurs when one language is preferentially impaired or recovered. Successive recovery is found when a language recovers only after the other recovering language has maximally recovered. Differential recovery occurs when one language recovers better than the others irrespective of premorbid proficiency. Antagonistic recovery, the least common pattern, is found when a language regresses when the other language recovers. Lastly, mixed recovery patterns occur, following more than one of those listed above.

Explanations for Recovery Patterns in Multilingual Aphasia

Since the late nineteenth century, a number of researchers (e.g., Ribot, Freud, Pitres, and Minkowski) have addressed the question of which language would recover first in multilingual or bilingual aphasia. In a general book on memory, Ribot (1881) hypothesized that the first acquired language (mother tongue) would recover first and best and the language acquired right before the brain damage would be impaired the most severely and recover slowly. In his book *On Aphasia* (1953, originally published in 1891), Freud, too, speculated that this pattern would manifest. Pitres (1983, originally published in 1895), by contrast, reported seven cases in which the most used language just before the injury, whether or not it was the mother tongue, recovered first and most completely. Complementing this debate, Minkowski (1983, originally published in 1927) and a few colleagues claimed the

importance of affective factors, reporting cases where bilingual aphasics would recover the language with the strongest affective ties first and most completely.

To date there appears to be no simple rule to account for recovery patterns in bilingual aphasics (Obler & Mahecha, 1991); among bilinguals, about equal numbers show greater impairment in their first (28%) and second (32%) languages (Fabbro, 2001). In addition to the factors of order of acquisition mentioned above, recent factors that have been nominated to predict performance in bilingual aphasia are premorbid language proficiency, age and contexts of language acquisition, and structural relations among languages (Marrero, Golden, & Espe-Pfeifer, 2002; Gil & Goral, 2004). A language with higher proficiency has a high likelihood to recover better than another language with lower proficiency. When premorbid proficiencies of two languages are comparable, bilingual individuals with aphasia tend to demonstrate parallel recovery. In terms of age of acquisition and contexts, a language acquired earlier tends to recover better than a language acquired later in life. Lastly, although language therapy is provided in one language, improvement in both languages may be expected, particularly if two languages share common underlying linguistic structures.

Cerebral Dominance in Bilinguals and Multilinguals: Data From Aphasia

Initially, researchers had believed that either the second language in bilinguals was superimposed over their first language in the language dominant hemisphere (the extended system hypothesis) or elements of each language were stored separately so that language was subserved by different networks of neural connection (the dual system hypothesis) (Obler, Hyun, Connor, O'Connor, & Anema, 2007; Lorenzen & Murray, 2008). The extended system hypothesis was supported by cases of parallel recovery and the dual system hypothesis was supported by cases of selective recovery in bilingual aphasics. Current neurolinguists suggest that overlapping, but also distinct, neural networks of different languages exist (the tripartite system hypothesis) (Obler et al., 2007; Lorenzen & Murray, 2008). Grammatically identical items and similar lexical items—often transparent cognates—in both languages will be stored together.

An additional candidate to explain differential recovery patterns in multilinguals with aphasia has been that they have more right-hemisphere involvement in language processing than monolinguals, or that they have more left-hemisphere dominance for languages learned better or earlier. In terms of lateralization of languages, of course, for nearly a century and a half it has been known that the left hemisphere is primarily responsible for language generally (e.g., Broca, 1865) in right-handers and even in most left-handers but that the right hemisphere participates as well (e.g., Hecaen and Albert, 1978). The data supporting this understanding come from individuals with aphasia whose status vis-à-vis multilingualism was often not explored or even mentioned. In such individuals, brain damage to the right hemisphere rarely resulted in the frank language problems associated with aphasia, whereas damage to peri-Sylvian regions on the left hemisphere did. The early reports that bilinguals tended to show more aphasia resulting from right-hemisphere damage (e.g., Gloning & Gloning, 1965) prove not to be representative when consecutive cases of multilingual aphasia are studied (e.g., April & Tse, 1977). Thus aphasia in bilinguals supports the standard understanding that, overall, the left hemisphere is dominant for the languages one knows.

Knowledge Acquired From Aphasia Therapy in Multilinguals

Speech-language pathologists evaluate receptive and expressive language skills and provide language therapies focusing on improving functional communication skills in aphasic individuals who know two or more languages. To evaluate the degree of language impairment, the Bilingual Aphasia Test (BAT, available at <http://www.mcgill.ca/linguistics/research/bat/>), developed by Paradis and Libben (1987), is commonly used. After collecting aphasic individuals' history of learning each of their languages, comprehension, production, reading, and writing skills are assessed in each one. Specific tasks are designed to investigate three different linguistic dimensions: linguistic levels (phonology, morphology, syntax, semantics), linguistic tasks (auditory comprehension, reading comprehension, speech production, writing, translation), and linguistic units (sounds, words, phrases) in each language. Additionally, this test reveals whether the deficit pattern is language-specific or central. Unlike other assessments used for monolingual aphasics, the BAT is assessed by a different speech-language pathologist for each language and assessed on separate days to inhibit other-language activation. Although code switching often occurs among multilinguals, pathological code-switching habits during the assessment are thoroughly described as well (Fabbro, 2001).

The following questions have been posed concerning therapy for multilinguals with aphasia (Paradis, 1993): (1) Which language should be used for language therapy? (a) Is it sufficient to treat only one language? (b) If so, which language should be treated? (c) Is it better to treat all languages? (2) Will therapy benefit transfer across languages, either only among structurally similar languages or else to structurally distant languages as well?

As a rule, one language is chosen by patients or their family depending on their needs or the availability of speech-language pathologists speaking a specific language. The theoretical question remains whether there is crosslinguistic generalization for therapy in one language, and, if so, whether directionality matters (e.g., Lx to Ly vs. Ly to Lx). Some researchers (e.g., Galvez & Hinckley, 2003; Meinzer, Obleser, Flaisch, & Rockstroh, 2007) report no generalization from the trained to the untrained language whereas others (e.g., Gil & Goral, 2004; Kohnert, 2004; Edmonds & Kiran, 2006) find generalization to the untrained language to some degree. For example, in the study of Galvez and Hinckley (2003) a late bilingual (exposed to the second language [L2] after age 18) received several phases of language therapy for aphasia that focused on improving picture naming in Spanish (L1) and English (L2). Although generalization of picture-naming performance to the other language modalities (e.g., verbal expression, auditory and reading comprehension) was observed within each language, no transfer to the other language was found.

Meinzer et al. (2007) also reported no transfer effect in an early-bilingual (exposed to L2 at the age of 3) aphasic speaking French (L1) and German (L2). Here, too, language therapy focused on picture naming in German. As in the results of Galvez and Hinckley (2003), the participant exhibited within-language generalization (in German, the treated language), but did not show generalization to French (the untrained language). Along with the behavioral study, functional MRI was performed to confirm the results of the behavioral study via observing changes of the participant's brain-activation pattern before and after treatment. Before language therapy, German picture naming mainly elicited right-hemispheric activation, but language therapy yielded activation of both hemispheres (suggesting bilateral reorganization). However, activated areas on the right hemisphere during French naming attempts were no different before and after language therapy.

In contrast, Gil and Goral (2004) reported that an individual with aphasia who was a late-bilingual Russian (L1) and Hebrew (L2, from age 35) speaker exhibited parallel recovery when they tested him at age 57, two weeks post-onset of his aphasia. After a

month of language therapy in Hebrew, this participant showed improvement in both languages to the same degree. However, when evaluated at five months post-onset, right after receiving therapy in his L2, his non-treated L1 showed significantly greater improvement than the treated L2. A somewhat different pattern of crosslinguistic generalization is seen in the study of Edmonds and Kiran (2006), where all three bilingual aphasics showed generalization within a trained language. However, although two out of three bilingual aphasics demonstrated crosslinguistic generalization to an untrained language, the third participant did not. More specifically, Kohnert (2004) found crosslinguistic (Spanish–English) generalization when cognates were trained, but this generalization was not found when non-cognates were trained.

Providing bilingual aphasia therapy with two languages would be ideal, but sometimes it is a challenge finding bilingual speech-language pathologists so choosing a language that can yield best results becomes crucial. However, there are not enough studies of bilingual aphasia therapy yet to determine which language should be used to promote transfer effects, although age of language acquisition, premorbid proficiency, language modalities, and shared lexicons are revealed to play a role in crosslinguistic generalization.

What Multilingual Aphasia Tells Us About Brain Organization for Language

While it is not possible to precisely predict the specific recovery pattern for a given multilingual individual with aphasia, a number of factors influencing the outcome have been nominated. Also, converging evidence from lateralization and imaging studies is often available to bolster the understanding that age and manner of acquisition, use patterns and proficiency achieved, and structural similarities among languages play a role in aphasia impairment patterns across individuals' languages and recovery patterns. What one can conclude from the literature on multilingual aphasics is that there is substantial variability in the ways different individuals instantiate the two or more languages they acquire. For the largest group—those with parallel recovery—it appears that the two or more languages are quite similarly organized in the brain, at least at relatively gross levels (at some level of individual cell networks, of course, there must be differences). This is consistent with the imaging work on healthy bilinguals and multilinguals. For others, however—perhaps more so for those who learn or acquire an additional language at an age beyond early childhood—the evidence from differential aphasia patterns suggests somewhat differing language-representation and language-processing networks for the different languages. While the right hemisphere does not seem substantially more involved in bilinguals' language processing before aphasia than in monolinguals, it may play a role in recovery from aphasia. Promising hints of cross-language generalization in therapy suggest relative interdependence of different languages' networks—perhaps particularly for related morphological and syntactic structures and for cognate words—while lack of such generalization in some studies suggests greater independence between the multilingual's language networks. Only when neuroscience evolves to permit testing of the language behaviors associated with specific neural networks will we be able to move our understanding of these patterns to a finer-grained level.

Multilingualism and Attitudes

PÁDRAIG Ó RIAGÁIN

Introduction

In the definition provided by Sarnoff (1970, p. 279) an attitude is “a disposition to react favourably or unfavourably to a class of objects.” In the case of language attitudes, the “class of objects” which give rise to such reactions are, of course, language related. The term can refer to cognitive (beliefs about the languages), affective (feelings toward languages), or behavioral (inclination toward certain language behavior) attitudes (Giles, Hewstone, & Ball, 1983). Thus attitudes, in a language context, can involve issues such as evaluation (how favorably a language is viewed), language preference (e.g., which of two or more languages is preferred for certain purposes or in certain situations), reasons for learning a particular language, evaluation of social groups who use a particular language variety, desirability of multilingualism and multilingual education, and opinions concerning language policies.

The study of language attitudes is part of the wider task of describing and accounting for the pattern and trends of languages in both local and global society. Unfortunately, the concept of “multilingualism,” which is frequently invoked in this context, is what the French sociologist Bourdieu (1991, p. 90) would call an “elastic” concept: “everyone can unconsciously manipulate [its] extension in order to adjust [it] to their interests, prejudices and social fantasies.” It is thus of little value for the purposes of contextualizing a discussion of language attitudes. A more useful approach is offered by de Swaan (1998, 2001), who views the global constellation of languages as a “system” with a recognizable structure.

The structural dimension of the global system of languages can be described and measured with regard to the number, location, and sociodemographic characteristics of those speaking the several thousand languages that comprise the system. The system is, according to de Swaan (1998, 2001), both a hierarchical and a nested pattern. The great majority of these languages are spoken by groups which are small in number and which, in total, constitute a relatively small percentage (ca. 10%) of the world’s population. A further 150 or so are spoken by populations which exceed 1 million. They include most of the official state languages of the world, and thus the majority of the lesser-spoken languages are “nested” within their political and communicative orbit. Among these more widely spoken languages, a dozen or so are spoken outside of their original core areas, and these de Swaan refers to as “continental” or “subcontinental” languages. Finally, one language—English—is deemed to be a “global” language.

The global language system is in a process of constant change. The dynamic dimension of the global language system can be initially measured by reference to patterns of second language acquisition. International surveys (e.g., Eurobarometer) suggest that, of the multiple possibilities on offer, only a relatively small selection of the world’s languages are learned as second or foreign languages. Few learn minority languages outside of the locality in which they are spoken and, as a rule, few state languages are acquired by persons outside of that parent state. However, languages placed higher up the hierarchy tend to fare better. These include the languages ranked as (sub)continental and, of course, the one truly global

language, English. Second (or third) language acquisition does not, in itself, lead to structural changes in the global language system and most mid-ranking languages appear stable in terms of numbers and relative rank. However, in those instances where second language acquisition leads to the displacement of the first, there is simultaneously a process of language attrition or shift and language spread.

The dynamics of language change are closely related to the general process of economic restructuring, currently known as "globalization." Processes of globalization are visible not only in the increased movement of goods and services across political borders, but also the migration of people. It is facilitated by a lowering of government impediments to such movements, and by technological progress in transportation and communications. The activities of states are thus designed to create the conditions necessary to promote economic competitiveness within the international economic order. These concerns impact on language attitudes by prioritizing continental and global languages, with the selection of particular languages reflecting existing and anticipated external trade, communication, and migration flows.

While economic concerns may thus lead to the learning of the more widely spoken languages—to levels where children will not, at the very least, be disadvantaged later in their educational and adult careers—globalization also stimulates counterdemands in many localities for the teaching of minority and regional languages. Many parents and communities argue that, if too much time and energy is devoted to the teaching of second or third languages, the child's first language and his or her general educational progress will suffer. The sense of the value of one's own language is a fundamental dimension of the sense of knowing the place which one occupies in social space. Thus the movement toward a new, more radical, phase of globalization and political integration is proceeding, side by side, with a growing reassertion of local, regional, and ethnic interests.

It is thus not necessarily the case that all dimensions of the attitudinal pattern in a particular situation will point in the same direction. For example, it is not unusual for some groups to both value their language as a marker of their group identity and, at the same time, hold negative views of it in terms of its utility and social prestige. Although this may seem contradictory, it may be perfectly understandable when the social and economic position of the language group is considered. Thus, the prevailing language attitudes in a given situation must be established by empirical research. It is to that question that the discussion now turns.

Theory and Method in Attitudinal Research

The contributions of several different disciplinary perspectives are of relevance. Attitudes in general, and language attitudes in particular, are of considerable interest to social psychologists, sociologists, and political scientists and anthropologists. The sociological and political approach to investigating language attitudes is characterized by survey and interview techniques in which the informants themselves report their attitudes. The first surveys in the developed world looking specifically at language attitude were conducted in Canada in 1965 for the Royal Commission on Bilingualism and Biculturalism (see Pool, 1973, for a detailed account). Two national sample surveys were conducted in 1965 among adults and teenagers. The surveys were primarily designed to collect information about opinions on a wide range of language-policy issues. At about the same time, Fishman and his associates were using similar methods to examine the attitudes of the Spanish-speaking community in New York (Fishman, Cooper, & Ma, 1971).

The Canadian research was followed in 1973 by a national language-attitudes survey conducted in Ireland (see Ó Riagáin, 1997, for details) and, later in the 1970s, by a number

of surveys conducted in Finland. In the 1980s, the Minority Languages Survey Project was undertaken in the UK among immigrant groups. The 1990s saw the geographical spread of language-attitude surveys become yet wider, with surveys in the Basque Country, Ireland, Friesland, Wales, and a number of other regions such as Galicia, Languedoc-Roussillon and Sorbia (see Garrett, Coupland, & Williams, 2003, for details of these and other surveys).

Within the social-psychological perspective, the indirect matched-guise procedure has been used most widely (Cargile, 2002). In this procedure, selected samples of listeners are told that they are to hear the voices of different speakers reading some neutral passage of text, and are then asked to form an impression of these speakers using a series of person-perception rating scales (e.g., intelligence, sincerity, etc.). Unknown to the listeners, all of the speech extracts are, in fact, produced by one speaker using realistic guises of different languages or speech characteristics. The first study using this indirect method was that of Lambert, Hodgson, Gardner, and Fillenbaum (1960). English Canadian and French Canadian subjects rated in-group and out-group speakers (i.e., English Canadian and French Canadian speakers respectively). English Canadians were found to view speakers of their own ethnic group as superior to those of the other ethnic group, while the French Canadian subjects seemed to have adopted the inferior position assigned to them by the majority culture around them. This first study precipitated an outpouring of further speaker-evaluation studies, the findings of which have recently been reviewed by Giles and Billings (2004), among others. Attitudinal research based on this work dominates within this disciplinary context. While "certain methodological and substantive assumptions have proven extremely tenacious," "many things have been added to the paradigm in the last quarter century" (Bradac, Cargile, & Hallett, 2001, p. 141).

Perhaps the more striking feature of work involving language attitudes over recent decades has been the emergence of a number of theoretical perspectives which subsume language attitudes within larger frameworks. Among these new developments may be mentioned those perspectives built around anthropological work on language ideology (Schieffelin, Woolard, & Kroskrity, 1998) and linguistic habitus (Bourdieu, 1991).

While language ideology is emerging as an important concept for understanding the politics of language in multilingual situations, the term "ideology" is used in different ways. As Schieffelin et al. note (1998, p. 58), "What most researchers share, what makes the term useful in spite of its problems, is a view of ideology as rooted in or responsive to the experience of a particular social position." Language ideologies are thus about more than individual speakers' attitudes to their languages, or speakers using languages in particular ways. Rather, they include the values, practices, and beliefs associated with language use by speakers, and the discourse which constructs values and beliefs at state, institutional, national, and global levels (Blackledge & Pavlenko, 2002, p. 122).

The complex ways in which language ideologies are produced and reproduced can also be understood in relation to Bourdieu's (1991) concept of habitus, understood as a system of lasting, transposable dispositions and attitudes which, integrating past experiences, functions at every moment as a matrix of perceptions, appreciations, and actions and makes possible the achievement of infinitely diversified tasks (Thompson, 1991, p. 12). These dispositions are formed primarily in childhood, especially in the home and school, by the internalization of the practices of adults which in turn reflect the family's social position. It follows, therefore, that strategies of language "assimilation and dissimulation" (Bourdieu, 1991, p. 64) are inevitably and unavoidably linked to the more general strategies of social reproduction adopted by groups and individuals (i.e., the strategies by which each generation endeavors to transmit to the following generation the social and economic advantages it holds).

Main Findings

The findings of this research have been generally consistent. In the social-psychological research,

speakers of “high” or “powerful” languages tend to be rated highly on competence and traits related to socio-economic status, while speakers of “low” or “powerless” languages are evaluated less favourably along these dimensions, even by judges who themselves have “subordinate” ethnic speech markers. (Giles et al., 1983)

Attitudes are not one-dimensional, however. Edwards (1999, p. 102) suggests that “two particularly salient evaluational categories account for most of the variance: social status and solidarity.” Thus, although lower-class, minority, and “provincial” speech styles often have positive connotations in terms of integrity and attractiveness, their speakers are typically assessed as being less competent, less intelligent, and less ambitious than are those who enjoy some regional, social, or ethnic majority status. More recent matched-guise research has incorporated this finding by using factor analysis to confirm the clustering of personal traits along these two dimensions (Woolard & Gahng, 1990, p. 312).

It might be noted in passing that this general finding, established with the “indirect” approach, is similar to the conclusions of those researchers using more direct methods. For example, the Irish language-attitude surveys report that

public support for Irish is shown to be very positive when attitudinal questions in surveys tap into the role the Irish language is perceived to have in defining and maintaining national cultural distinctiveness. While there is a weak relationship between this dimension of the attitudinal pattern and actual language use, . . . the general population is willing to accept a considerable commitment of state resources to ensuring its continuance and even to support a considerable imposition of legal requirements to know or use Irish on certain groups within the society, such as teachers and civil servants. [However] for most people, it is within the educational system that they have the most direct contact with Irish language policy. Not surprisingly, given the relationship between educational achievements and the qualifications needed for entry into the largely English-speaking labour market, the public are not prepared to support policies which would discriminate strongly in favour of Irish. (Ó Riagáin, 1997, p. 279)

Finally, it might be noted that there have been numerous studies of the relation between attitudes and achievement in language learning. The basic premise underlying attitudinal research in second language acquisition studies is that language is a major defining attribute of a group of people, and, thus, to learn a language involves some degree of identification with the group that speaks it. That is, language is more than a symbolic system that facilitates communication. Language is a defining behavioral feature of a cultural group, and thus acquiring the language involves taking on patterns of behavior of that group. As a consequence, an individual’s attitudes toward that group and toward other cultural groups in general will influence his or her motivation to learn the language, and thus the degree of proficiency attained (see Gardner, 1985, 2002, for a more detailed review of this literature).

Conclusions

According to Bourdieu (1991), it is part of the practical competence of speakers to know when, where, and how to speak one language rather than another in order to derive a “profit” most advantageous to their interests. As Fishman (1977, p. 114) observed,

Languages that are not being imposed by force, must provide (or promise to provide) *entrée* to scarce power and resources or there would be little reason for indigenous populations to adopt them for intergroup use . . . Languages are rarely acquired for their own sake.

In a multilingual situation, the distribution of linguistic capital is thus often related to the distribution of other forms of capital which together define the location of speakers and communities of particular languages within the overall social hierarchy. In the early 1980s, in a review of attitudinal research at the time, it was observed that "in every society the differential power of particular social groups is reflected in language variation and in attitudes toward those variations" (Ryan, Giles, & Sebastian, 1982).

Lest it be thought that this theoretical approach points to the ultimate domination of the national "market" language, it should be noted that the market metaphor also allows for the possibility that, in certain circumstances, minority languages can survive and prosper. A language competence can be accorded a value in local or regional contexts that it is denied in the national or international market, in a way analogous to the viability and durability of local markets within national economic markets. And language markets can be influenced by political interventions. (It might be noted here that there are some marked affinities between Bourdieu's notion of the "linguistic market," and de Swaan's notion of a "global language system.") On the other hand, it is also the case that linguistic markets are more and more *international* and overlap language borders. Therefore, neighboring and international languages play an increasingly important role in national and local settings.

The structure of the linguistic market or system—local, national, or international—therefore obviously defines the acceptability and desirability of a language. It follows, therefore, that language attitudes and strategies of language learning and use are inevitably and unavoidably linked to more general social strategies of individuals and communities. The very anticipation of such strategies may, in fact, carry implications for language behavior in advance of any actual mobilization, be it social or spatial.

While these theoretical insights are broadly consistent with empirical research, it has also to be acknowledged that there are still a number of major gaps in that research corpus. Research on language attitudes has fractured along the same lines as much of applied linguistics research. That is to say, while there are good studies of attitudes in minority-language contexts, and in national and international contexts as regards attitudes to foreign and global languages, there are not many good examples of studies which look at attitudes across the full hierarchical range of multilingual settings.

Furthermore, as Giles and Billings note (2004, p. 188), while academics from many disciplines agree that language attitudes are an important enterprise, they differ widely with regard to the theories and methods chosen to analyze such attitudes. All research methods have their advantages and their limitations. There is currently an urgent need for research approaches which combine several methods in a single piece of research, on a scale not heretofore attempted, and using each to supplement and check on the others.

Third, there is a need to track changes in language attitudes over time in a more systematic and organized way. One example of changing language attitudes comes from Woolard and Gahng (1990), who collected speaker-evaluation data in Barcelona in 1980 and then again with a matched sample in 1987. But such examples are not yet very common.

Finally, there are few examples in attitudinal research of comparative analyses across a number of states. In the past, comparative research was inhibited by the absence of good-quality data. But there are now a growing number of international surveys which include language-related questions, including some on attitudes. Within Europe these include the Eurobarometer series, the European Social Surveys, and the European Values Surveys.

International surveys with a wider coverage include the International Social Survey Programmes and the World Values Surveys. One looks forward to studies which will exploit the possibilities of these data banks for comparative research in the area of language attitudes.

Multilingualism and Emotions

JEAN-MARC DEWAELE

Introduction

Wierzbicka (2004) notes that “emotions are central to human life, and bilingualism provides a new perspective on emotions which promises to lead to new insights, as well as to offer crucial evidence for the old debates” (p. 94). One of these debates opposes researchers who defend a more universalist perspective on emotions and researchers who favor a more relativist perspective. Wierzbicka (2004) defends the latter position, arguing that the vocabulary of emotions differs from language to language, which means “that the set of concepts by means of which the speakers of any given language make sense of their own and other people’s feelings is specific to a particular language” (p. 94). She points to the different set of conceptual categories for Polish and English emotion concepts which means that Polish and English speakers classify and interpret their own and other people’s feelings differently and that their emotional lives are likely to be different, to some extent (p. 95). Reflecting on her language preferences when talking to—and about—her baby granddaughter, she explains that she definitely prefers Polish, her first language (L1), rather than English, her second language (L2), because of the emotional force of the L1 words with multiple diminutives and the fact that the Polish words fit the way she thinks and feels about the baby. The English emotion words leave her cold and do not feel “true” (p. 101). She feels that Polish emotion scripts are much more emotional than English ones. When she speaks in English about her baby granddaughter, she makes a conscious effort not to sound excessively emotional, which restricts her ability “to speak freely as much as the lack of adequate English words does” (p. 101).

Wierzbicka’s observations raise a number of crucial questions on the link between multilingualism and emotions, which will be considered in more detail:

1. Are basic emotions universal, or are they shaped by local culture and language?
2. Do multilinguals prefer to express strong emotions in their L1?
3. What is the status and nature of emotion words and emotion-laden words in the bilingual lexicon?

Emotions: Universal or Relative?

Pavlenko (2008) offers a way out of the difficult debate linked to the first question by proposing a definition of emotion concepts that combines both biological and sociocultural elements. For her, emotion concepts are “prototypical scripts that are formed as a result of repeated experiences and involve causal antecedents, appraisals, physiological reactions, consequences, and means of regulation and display” (p. 150).

She argues that these concepts are embedded within larger systems of beliefs about psychological and social processes (p. 150). The fact that concepts may be different in two languages does not imply that speakers of these languages have distinct physiological experiences: “Rather, it means that they may have somewhat different vantage points from which to evaluate and interpret their own and others’ emotional experiences” (Pavlenko,

The Encyclopedia of Applied Linguistics, Edited by Carol A. Chapelle.

© 2013 Blackwell Publishing Ltd. Published 2013 by Blackwell Publishing Ltd.

DOI: 10.1002/9781405198431.wbeal0795

2008, p. 150). Her own work on Russian–English bilinguals has shown that some emotion concepts vary across these two languages in terms of function, encoding, and salience (Pavlenko, 2002). She found that in English emotions are viewed as states and expressed by means of adjectives while in Russian emotions are viewed as processes and expressed with verbs. A study on American learners of Russian showed that, despite their awareness of the core meaning of the language-specific Russian emotion verb *perezhiivat* ‘to experience things keenly’, they did not use this verb in the narrative tasks (Pavlenko & Driagina, 2007). This suggests that they had not yet internalized the new conceptual category and needed to acquire new lexicosyntactic frames. They had to learn to use verbs and adverbial constructions, presenting emotions as processes, while the Russian learners of English needed to use adjectival constructions, presenting emotions as states (Pavlenko & Driagina, 2007, p. 228).

The Language of the Heart

Much of the early work in the field has pointed to the more limited emotional resonance of the L2 compared to the L1. Marcos (1976) named the emotional detachment that bilinguals often have in their L2 as the “detachment effect.” According to him, the L2 fulfills an intellectual function and is relatively devoid of emotion; whereas the L1 clearly expresses emotions.

Bond and Lai (1986) examined language choices of female Chinese students in a Hong Kong university who had been asked to interview each other in L1 Cantonese or L2 English on two neutral and two potentially embarrassing topics. The first topic was economic, the second was political, the third was sociological (differences in sexual attitudes between Chinese and Westerners), and the fourth was potentially more emotional, namely a personal story about a recent embarrassing episode. The study showed that more English was used in the discussion of the latter two topics. The authors interpret this as an indication that the use of the L2 allowed participants to distance themselves more from the embarrassing topic. In a similar vein, Javier and Marcos (1989) reported that code switching to an L2 allowed participants to distance themselves from what they were saying, hence reducing their anxiety. Both studies have been widely cited as evidence of the existence of a “detachment effect” of the L2.

There is abundant evidence from the autobiographical works of bilingual writers that the L1 typically has the strongest emotional connotations. Rosario Ferré, for example, a Puerto Rican writer, describes Spanish (her L1) as her language of the heart:

Spanish still makes me suck faster at life’s breast . . . I can roll on the ground and frolic in Spanish because I don’t have to worry about anything; words always mean what they say. I love to make love in Spanish; I’ve never been able to make love in English. In English, I get puritanical. (Quoted in Kellman, 2003, pp. 137–8).

Schrauf (2000) noted that memories from childhood and adolescence that were experienced in the L1 are typically richer in terms of emotional significance when recalled in that specific language. When immigrants recall L1 memories from childhood in an L2, some emotional intensity is lost (Schrauf & Rubin, 1998). Schrauf and Durazo-Arvizu (2006) have argued that bilinguals recalling a particular memory engage unconsciously in the mental reconstruction of an event that was originally encoded into memory in a determined sociocultural and linguistic environment. The emotional tone of the event and perhaps some explicitly remembered words or phrases in the L1 or L2 are encoded as well.

Pavlenko (2005) argues that different languages can have different affective meanings depending on the interlocutors and the situation. In other words, the L1 is not always the

language of intimacy and the L2 the language of detachment: "Speakers may use these languages to index a variety of affective stances, and they may also mix two or more languages to convey emotional meanings" (p. 131).

Her own study on language choice in emotional exchanges between multilingual parents and their children (Pavlenko, 2004) showed that language dominance is the key factor affecting language choices, overall and in emotional expression. Parents who were dominant in the L1 reported a preference for L1 in communication with the children, but those dominant in an LX (any language which is not the L1) were less likely to use the L1. She found a strong emotional tie of many parents to their L1 and hence their preference to use that language with their children. However, some parents reported feeling perfectly comfortable communicating in their L2 with their children, though they reported switching occasionally to their L1 when feeling very emotional. Other parents reported the opposite pattern, using their L1 with their children, but switching to the L3 (the partner's L1) to scold the children because they would react faster. Positive and negative emotions were linked to different language choices.

In a series of studies based on a corpus of data collected through the Bilingualism and Emotions Questionnaire (BEQ; Dewaele & Pavlenko, 2001–3) from more than 1,500 multilinguals on their different languages and a corpus of interviews with 20 multilinguals (Dewaele, 2011), a number of interesting patterns emerged concerning language choices and perceptions (Dewaele, 2004a, 2004b, 2006, 2008, 2010, 2011).

Dewaele (2008) looked specifically at the perceived emotional weight of the phrase *I love you* in the multilinguals' different languages. A majority of speakers reported that *I love you* was strongest in their L1, a third reported that the phrase was equally strong in their L1 and an LX, and the remaining quarter of participants said that the phrase was stronger in an LX. This is an indication that the language of the heart can shift. Statistical analyses revealed that the perception of emotional weight of the phrase *I love you* was associated with self-perceived language dominance, context of acquisition of the L2, age of onset of learning the L2, degree of socialization in the L2, nature of the network of interlocutors in the L2, and self-perceived oral proficiency in the L2.

Dewaele (2010) presented a systematic analysis of the effect of three clusters of independent variables (participants' linguistic history, present language use, sociobiographical and psychological variables) on language perception and language choice for the communication of feelings in general, for anger and swearing, as well as self-perceived proficiency and foreign-language anxiety. Later starters reported lower levels of self-perceived competence in oral and written skills. They also tended to use the LX less frequently to communicate emotions; they rated the positive characteristics of the LX lower and reported higher levels of foreign-language anxiety in different situations. LXs that had been acquired only through formal classroom instruction were used less frequently to communicate emotions than LXs that had been learned naturalistically or which had also been used in authentic interactions outside the classroom (mixed context). The same pattern emerged for self-perceived competence and FLA in different situations: Instructed learners felt less competent and more anxious than mixed and naturalistic learners. It thus seems that context of acquisition resonates for years after the end of the active "learning phase" of the LX.

Frequency of use of the LX was the independent variable with the strongest effect on self-perceived proficiency, language choice to express emotions, perception, and foreign-language anxiety. Data from the interviews suggested that frequent users of an LX gained confidence and stopped worrying about their accent or possible errors.

LX socialization was linked to increased use of the LX to express emotions. The highly socialized LX user can express emotions in the LX competently and confidently, but it takes years before the positive language characteristics and emotional strength of swear-words in the LX equal those of the L1. Some Asian participants reported that it took them

many years living in an LX environment before they dared to use some of the swearwords in that LX, and typically only mild swearwords. There was also considerable variation between individuals, with cultural background playing an important role in perception and use of emotional language. Participants with larger networks of interlocutors in an LX were also more likely to use that LX for the communication of emotions, and their perceptions and foreign-language anxiety evolved toward that of their native-speaker interlocutors.

The knowledge of more languages was linked to lower levels of foreign-language anxiety and higher self-perceived proficiency in the different languages. Language knowledge also had a positive effect on the communication of emotion and the perception of characteristics of the LX.

Participants who scored high on trait emotional intelligence reported lower levels of foreign-language anxiety across situations which could be linked to a stronger belief in the ability to communicate in different languages and a stronger ability to judge the emotional state of their interlocutor and to adapt their linguistic behavior if necessary (Dewaele, Petrides, & Furnham, 2008). An analysis of participants' comments suggested that many speech acts are culture-specific (Dewaele, 2010). Raising the voice in anger may be considered acceptable in southern Europe, but it is taboo in Asia. Bicultural multilinguals have a unique capacity to navigate between the taboos and sometimes conflicting sociopragmatic norms. They reported strategic use of code switching with other multilinguals, especially when talking about more emotional topics with familiar interlocutors. However, multilinguals also reported uncontrolled code switching in cases of strong emotional arousal. It seems that multilinguals can exploit their multicompetence to develop multilingual speech acts and emotion scripts that are quite unique to them, or shared by their partner, family, or ethnic group. A striking finding was also the dynamic aspect of language choice to express emotion (Dewaele, 2010). A growing awareness of sociocultural and sociopragmatic norms in the LX is linked to an evolution in users' repertoire for expressing emotions in the LX.

Because multilinguals tend to feel most proficient in their L1 (Dewaele, 2010), it is difficult to distinguish proficiency effects in language preference from other possible effects. In order to control the proficiency variable, Dewaele (2011) focused on a subsample of bi- and multilingual adults from the BEQ who declared to be maximally proficient in their L1 and L2, and used both languages constantly. The analysis revealed that, despite their maximal proficiency in the L1 and L2, participants preferred the L1 for communicating feelings or anger, swearing, addressing their children, performing mental calculations, and using inner speech. The L1 was also perceived to be emotionally stronger than the L2 and participants reported lower levels of communicative anxiety in their L1. Interview data from 20 multilinguals confirmed the finding that the L1 is usually felt to be more powerful than the LX, but this did not automatically translate into a preference for the L1. Longer immersion in the LX culture was linked to a gradual shift in linguistic practices and perceptions where the LX started to match the L1 in their hearts and minds.

The Nature and Status of Emotion Words in the Bilingual Lexicon

Pavlenko (1999) argued against the conflation of semantic and conceptual levels of representation in contemporary models of the bilingual lexicon and proposed to distinguish between lexical, semantic, and conceptual levels of representation. Referring to her research on the English emotion concept of privacy that is absent in the Russian of monolinguals but starts appearing in Russian-English bilinguals, she emphasized the dynamic nature

of the bilingual conceptual store and called for more attention to crosslinguistic and cross-cultural differences in conceptualization of different phenomena (p. 225). Pavlenko's call was answered by Caldwell-Harris and associates who started investigating the link between emotion words in the two languages of bilinguals and their physiological responses. Harris, Ayçiçeği, and Gleason (2003) found that different types of words elicit different galvanic skin responses in both monolingual and Turkish-English bilingual speakers, with taboo words and reprimands eliciting the strongest responses. Several bilinguals commented in the debriefing session that they could hear, in their mind, family members addressing reprimands to them. A comparison of the adult offspring of Latin American immigrants in the USA, for whom English was considered L2 but was the dominant language, and more recently arrived immigrants from Latin America to the USA showed that only the latter group reacted more strongly to reprimands in Spanish. The early learners of English had similar patterns of electrodermal responding in their two languages (Harris, 2004).

A follow-up study with Turkish-English bilinguals residing in Istanbul showed that emotional phrases presented in an L1 elicited higher skin conductance responses than emotional phrases in an L2 (Caldwell-Harris & Ayçiçeği-Dinn, 2009). The researchers also looked more specifically at emotion memory effects (i.e., the fact that emotion words are more frequently recalled than neutral words) among Turkish-English students from Istanbul University (Ayçiçeği-Dinn & Caldwell-Harris, 2009). They found that overall emotion-memory effects were similar in the two languages, with reprimands having the highest recall, followed by taboo words, positive words, negative words, and finally neutral words. The authors have advanced the "emotional contexts of learning hypothesis," arguing that language emotionality is independent of age of onset of acquisition, but linked to the emotional context in which the language was acquired and used (Harris, Gleason, & Ayçiçeği, 2006, pp. 276–7).

Altarriba and Canary (2004) used the word-priming paradigm to investigate the effect of word arousal on the priming effect in bilinguals. The authors found evidence of affective priming in both English monolinguals and Spanish-English bilinguals. However, bilinguals had longer reaction times and a reduced priming effect in some conditions when compared to monolinguals. The authors suggest that this difference might be linked to the fact that the bilinguals had learned and used English in educational and work-oriented environments and that their English emotion words had fewer emotional connotations and reduced affective priming (Altarriba & Canary, 2004).

The emotional Stroop task has also been used to investigate bilinguals for differences in processing emotion words. The emotional Stroop task is similar to the traditional Stroop task but the printed words are emotionally charged and do not label specific colors. Participants are asked to report the color of each word instead of the actual words. Emotions typically have an interference effect resulting in an increase in reaction times on the color-naming task. Sutton, Altarriba, Gianico, and Basnight-Brown (2007) used this method with highly proficient Spanish-English bilinguals. The researchers found evidence of interference in emotion words on the emotional Stroop task: Participants had shorter reaction times with neutral words as compared to emotion words in Spanish and English, illustrating that emotion words captured attention regardless of the language in which they appeared.

Conclusion

The picture that emerges from research on multilingualism and emotions is a complex and highly dynamic one. It suggests that multilinguals' language choices to communicate emotions and their perceptions of their various languages are partly linked to their past experience with these languages, partly linked to their current use of various languages,

and partly linked to a range of sociobiographical and psychological factors. All these factors interact and may cause conceptual shift reflected in different linguistic behavior. Moreover, emotion words and emotion-laden words can gain or lose their power over time. Finally, it seems that, while the L1 is the language of the heart for many multilinguals, it is not necessarily a permanent one.

Multilingualism and English

EVA ALCÓN AND MARIA PILAR SAFONT JORDÀ

The overwhelming spread of the English language around the world has given rise to various phenomena, such as the recognition of New Englishes varieties, multilingualism, and multilingual education. In this last case, existing educational models have been modified to account for multilingualism with English. This entry will deal with multilingualism with English from an educational perspective. In so doing, we will describe the presence of English in education on the basis of Cenoz's (2009) continua of multilingual education.

Education has always played a role in society, but it is also influenced by social trends. In the area of languages, the worldwide spread of a neoliberal market economy and the movement toward a globalizing world has influenced the spread of English. English is now well established in business, scientific conferences, and international cultural and political events, among many other areas. The increasing expansion of English has been visualized in terms of three concentric circles (Kachru, 1992). The inner circle includes countries such as Australia, Canada, the UK, Ireland, the USA, and New Zealand, where English is the first language for the majority of the population. The second circle includes countries where English is used at an institutional level as a result of colonization, such as Nigeria, the Philippines, and India. Finally, the so-called expanding circle includes many countries such as those in Continental Europe where English does not enjoy official status and is taught as a foreign language. From a quantitative point of view, Crystal (1997) claims that there are roughly between 320 and 380 million speakers of English in the inner-circle countries. In outer-circle countries there are between 150 and 300 million second language speakers of English, and 100 to 1,000 million learners of English in the expanding circle. Besides, the degree of contact between languages in the three circles can also explain why the number of English non-native speakers is substantially larger than its native speakers (the relationship is about four to one). English is also the language used in information and communication technologies and it is perceived as the most important language to be learned. For instance, the Eurobarometer report (European Commission, 2006) shows that, although the recognition of the benefits of competences in languages is increasing in Europe, English is perceived to be the most useful language to know: 68% of Europeans choose English as the most useful language, followed by French (25%) and German (22%). The position of English is even more apparent when respondents were asked which languages they thought children should learn. In this case, 77% of Europeans consider English to be the language that children should learn as a foreign language, 33% of respondents mention French, and 28% German. As a result of the global expansion of English, being proficient in English has become an important goal in education.

From an educational perspective, we can claim that, until the 1980s, English, together with other languages such as French, was introduced as a foreign language, and linguistic and cultural aspects of the English language were included on the curriculum of secondary education. At that time, English was viewed as the language of a few powerful countries and identification with British or American culture was assumed. From this perspective, proficiency in English was understood as a sign of greater economic and social power, and in countries such as Italy or Spain, children whose families had a higher economic status were sent to private classes of English and to summer schools in England or North

America. In addition, a monolingual approach toward language learning was the norm, the native speaker was seen as the model to follow, and criticisms regarding the expansion of English at the cost of other languages started to appear at scientific events.

Since the 1990s learning foreign languages, and particularly English, has been a priority in education. However, we can claim that there has been a shift in emphasis from linguistic uniformity and learning English as a foreign language from a monolingual perspective toward multilingual education with English. The debate on whether the use of English is a threat to other languages or not is still present in the field of applied linguistics. Thus, while Phillipson (1992) and Mühlhäusler (1996), among others, are pessimistic about the effect of the massive use of English on linguistic diversity, Alcón (2007), among others, supports the use of English as a world language, an international language, or a *lingua franca*. The level of resistance to English-language use and learning can be understood from a monolingual perspective of "one nation/one language, plus English as a foreign language," but not from a perspective of multilingualism with English. This perspective is in line with the aim of the European Commission to promote multilingualism, and different measures have been developed to promote it. Among them, the Commission document promoting language learning and linguistic diversity entitled *An Action Plan 2004–2006* (European Commission, 2003) was designed to indicate that English alone is not enough and encourages European citizens to have practical skills in three languages: their mother tongue plus two others. One can observe that in Continental Europe multilingualism is the norm and English is the second or the third language in the curriculum, either as a subject or as a medium of instruction. Similarly, English is now introduced in bilingual education together with the national language in countries such as China, Chile, Colombia, or Mongolia.

Multilingual education with English is an approach to linguistic education that can be explained within the continua of multilingual education suggested by Cenoz (2009). According to Cenoz (2009, p. 32), "multilingual education implies teaching more than two languages provided the schools aim at multilingualism and multiliteracy." On the one hand, this definition of multilingual education allows us to consider whether English becomes a second, third, or additional language on the curriculum, as well as the time and resources devoted to it. On the other hand, the author claims that at least four variables need to be considered in the continua of multilingual education: subject, language of instruction, teacher, and school context. Using these variables to analyze the introduction of English into education from a multilingual perspective, we can claim that English is nowadays a compulsory school subject, although differences may be found in the integration of English with the national, regional, and other foreign languages. In this sense, the early introduction of English, the number of hours devoted to English, coordination between language teachers, and negotiation of the syllabus in the school subjects are some of the issues that play a role in fostering multilingualism with English.

Another important variable for evaluating multilingual education with English is the implementation of content and language integrated learning (CLIL), which has been gaining importance since the 1990s. Despite the language policies of the European Commission, the implementation of CLIL may be explained by the results taken from SLA studies conducted in immersion and bilingual educational contexts in the USA and Canada. According to Dalton-Puffer and Smit (2007), the primacy of meaning over form, the conditions for naturalistic language learning, the amount of target-language exposure, saving time, and the positive affective consequences have been some of the arguments given for the implementation of CLIL. However, care should be taken in generalizing results from CLIL research to different educational contexts. In our opinion, the arguments for implementing CLIL lack the backing of context-based research. For instance, in immersion contexts, Krashen's (1985) input hypothesis and Long's (1996) interaction hypothesis were

validated by reporting the benefits of comprehensible input. In addition, Swain's (1995) output hypothesis was examined and the importance of form–meaning connections was found. In the future, the CLIL context as a social setting where language learning takes place requires further analysis. In this line, Coyle (2007) calls for a reconceptualization of the role of language, suggesting an approach which combines learning to use language and using language to learn. Although these remain the tenets of communicative language teaching and its implementation by means of a task-based approach, it might be useful as a framework to analyze language learning in CLIL classrooms. In addition, research conducted to date explores whether the CLIL context provides the conditions for English-language learning. As a result of this research, we are likely to gain an awareness of the specific conditions for language learning in CLIL contexts as well as information about what aspects of language can and cannot be practiced in this learning environment. For instance, García Mayo (2009) and Muñoz (2007) report that, although opportunities for real communication are provided, focus on form seems to be a need for language learning in CLIL contexts (see also Llinares García & Dafouz, 2010, for an overview of the main CLIL and bilingual projects that are being officially implemented in the Madrid Autonomous Community). Similarly, studies dealing with the development of pragmatic competence indicate that the language that learners are exposed to and are required to use in CLIL contexts is pragmatically removed from language use in natural settings. In this line, Dalton-Puffer (2005) explores how interpersonal aspects of communication are realized in the performance of directives and the way in which contextual factors such as the object of directives (information or action) or classroom register (instructional or regulative) affect speakers' directness choices. The results of this study show that these contextual factors interact systematically with the use of directives. In the same vein, Nikula (2008) presents a discourse-pragmatic analysis of classroom interaction. Nikula (2007) focuses on the IRF (initiate response feedback) structure in CLIL settings versus its use in EFL classrooms. Results showed that the IRF pattern is common in both classroom settings but, while the IRF sequences follow one another in EFL contexts, IRF sequences tend to be more loosely structured in a CLIL environment, in terms of turn length, teacher evaluation, and students' follow-ups (Nikula, 2007). These differences seem to suggest that discourse practices in CLIL environments offer students more opportunities for active participation (take the floor, initiate, interrupt) than those in EFL classrooms.

Taking into account the above-mentioned research findings as well as findings reporting the positive attitudes toward language learning triggered by CLIL programs (Lasagabaster & Sierra, 2009), it seems that a range of teaching practices need to be further implemented in different educational contexts (see also Ruiz de Zarobe & Jiménez Catalán, 2009; Lasagabaster & Ruiz de Zarobe, 2010). Yet, to achieve this, it must be mentioned that most of the time learners will face the learning of English by borrowing communication and learning strategies from the experience of acquiring other languages. Thus, they may benefit if the school includes a multilingual approach with English within its educational project. This leads to considering the third variable in the "continua of multilingual education": the teacher. Without any doubt, the language proficiency of teachers is a requirement both to teach English as a subject and to use it as a language of instruction. However, teachers' attitudes toward English need to be considered within the framework of a multilingual approach with English. The globalization and internalization processes have also changed the way in which teachers look upon English. English as a second or foreign language is being replaced by English as a language for global communication, or English as a *lingua franca* (ELF). Describing distinctive features of ELF at a phonological (Jenkins, 2000; Pickering, 2009), lexico-grammatical (Seidlhofer, 2009), and pragmatic (House, 2009) level has helped to move English-language analysis from the native speakers' perspective to that of the intercultural speaker. All of these studies report that ELF users are

successful in accomplishing understanding, and thus they cannot be described as “deficient communicators” (Firth, 2009). From this point of view, there are also some implications for the practice of English-language teaching and learning (see McKay, 2008, for a re-examination of English-language teaching assumptions). It seems that the main concern in teaching ELF is to provide learners with knowledge and opportunities to use English, the goal being to prepare citizens to make use of English when other communicative means are absent. In other words, emphasis is placed on the use of English as a direct mediator between participants in a discourse that would otherwise have to rely on translation (House, 2002).

Additionally, teacher training in multilingualism and multilingual teaching should be considered when analyzing this third variable of the continua. Truly multilingual teaching approaches would allow for the development of multiliteracy (Edwards, 2009). The concept of literacy as the ability to read and write in one language is now challenged by more sophisticated views that regard literacy as social and cultural in nature (Rosowsky, 2008). According to the “new literacy studies” movement (Pahl & Rowsell, 2006), there is a need to shift from a focus on only one dominant language to a broader view that includes cultural and linguistic diversity. In this sense, Edwards (2009) argues for the use of the term *multiliteracies*, which should also consider knowledge of the use of new technologies for communication. Following this view, the parts-to-whole or whole-to-parts dichotomy in literacy training would be replaced by *multipart-to-multi-wholes* or *multi-wholes-to-multiparts*. In these cases, children may be taught to read and write in more than two languages at the same time and under the same instructional context. The notion of *multiliteracies* is in line with the view that languages are not kept separately in the child’s mind; rather, they could all be part of a common underlying proficiency.

Bearing this idea in mind, some authors have argued for a multilingual approach to language instruction, namely that of *translanguaging* (García, 2007; Creese & Blackledge, 2010). This approach involves the use of more than one language in what is termed *flexible bilingual pedagogy*. The use of two languages in assemblies or classroom discourse would illustrate a bilingual reality that goes beyond the school. Some instances of these innovative teaching practices are provided by Creese and Martin (2008), who point to the use of bilingual pedagogical resources. Nevertheless, in these cases, English is the language of the speech community in which schools are located. In cases where English is the third language, *translanguaging* may imply the use of three languages along with the instructional process. It would be interesting to adapt such teaching approaches to the instruction of English in combination with the other two languages in a bilingual speech community, such as one of the bilingual regions in Europe.

Finally, there will be differences among schools when looking at the presence of English. The fourth variable in the continua of multilingual education, the school context, may also help to foster multilingualism with English. As reported by Cenoz (2009), this variable refers to the languages employed inside the school by teachers, staff, students, and even parents. Here, not only institutional discourse but also informal conversations, meetings, or written information may be analyzed to identify the degree of multilingualism of a given educational center. As argued by the author, if more than two languages are used for the above-mentioned purposes then the school may be considered as “more multilingual.” One aspect that is taken into account is the linguistic landscape of classrooms. In fact, the linguistic landscape may be considered a source of input, as acknowledged by Cenoz and Gorter (2008). According to these authors, the role of the linguistic landscape in the acquisition of the English language cannot be ignored. Despite the fact that the extent to which learners benefit from it may be difficult to control, the linguistic landscape presents authentic and contextualized input, and should thus be considered in fostering multilingualism with English.

Multilingualism and Higher Education

WALDEMAR MARTYNIUK

Introduction: Monolingualism—Plurilingualism— Multilingualism

Monolingualism is a term that refers to an individual person's ability to use one language only or to a community or society or nation or state where only one language is used as a means of communication. In reality however, these two situations are rather rare. In practice, most—if really not all—people grow plurilingual, that is, they notice the need for and build up their natural ability to handle several communication codes or at least several—regional or social—variants of one code bearing the name of this or that language. In practice then, most—if not really all—communities, societies, nations or states are—to a different extent—multilingual in the sense that their members use more than one language or language variant for communication purposes. Multilingualism then, refers to the coexistence of different languages in a given society. Plurilingualism “refers to the repertoire . . . of language which many individuals use, and is therefore the opposite of monolingualism . . . Thus in some multilingual areas some individuals may be monolingual and some may be plurilingual” (Beacco & Byram, 2007, p. 7).

The oldest and biggest European intergovernmental organization—the Council of Europe whose work in the area of languages and language education encompasses currently 47 European states as permanent members and several other states, including the USA, Canada, Japan, and Mexico as observers—is promoting strongly the notion of plurilingualism as an important human value indicating the need to protect the individual language ability and considering the right of every person to receive adequate support within the state educational systems in order to develop this ability to the most appropriate level to ensure personal success and proper contribution to the society.

The other intergovernmental organization in Europe—the European Union with its 27 member states—promotes multilingualism using the term in both its above mentioned meanings: as individual ability (plurilingualism above) and social phenomenon.

In this entry we give a brief account of European policies related to plurilingualism/multilingualism in higher education (HE).

Multilingualism in Higher Education: Promoting Civilization and Competitiveness

The aim of higher education is to promote both civilization and competitiveness—in the sense that it involves knowledge, skills, and attitudes of students as individual human beings and as contributors to society. While preparing students for employment, shaping them as active participants in the life of their societies and supporting them in their personal development and the development and maintenance of a broad knowledge base are equally important (Bergan, 2005). There seems to be a broad agreement that these two aspects need to be kept in balance and complement each other.

2 MULTILINGUALISM AND HIGHER EDUCATION

The efficiency of educational systems, most specifically in higher education, relates to the degree they are able to identify and develop further the qualities and abilities “brought in” by the students and—based upon those—to offer access to new areas by presentation of new exploration tools. Language competences play an important role in both of these processes.

Multilingualism in higher education may be viewed both as a state of affairs and a policy. In both aspects it is related to processes of globalization and internationalization of HE.

Globalization and Internationalization of HE

Globalization of HE implies the widening, deepening and speeding up of worldwide interconnectedness—subject to and result of free market development (OECD, 2009, p. 18).

Internationalization of HE indicates relationships across borders between nations, or between single institutions situated within different national systems—subject to national culture and government, while it is also an instrument of the “competition state” in the global setting. Trends to internationalization and to globalization continually reinforce each other (OECD, 2009, pp. 21–3).

Higher education enhances and is driven by globalization. It trains the highly skilled workers and contributes to the research base and capacity for innovation that determine competitiveness in the knowledge-based economy. It facilitates international collaboration and cross-cultural exchange. Even if not all universities are (particularly) international, all are subjects to the same processes of globalization—“partly as objects, victims even, of these processes, but partly as subjects, or key agents, of globalisation” (OECD, 2009, p. 18).

The OECD reports the following trends in higher education to 2030:

- cross-border higher education, implying mobility of students, faculty, and institutions, will grow;
- academic research will become increasingly international and will continue to be affected by both collaborative and competitive forces;
- higher education systems in Asia and Europe will gradually increase their global influence, although North America will continue to hold a clear advantage especially with regard to research (OECD, 2009).

Multilingualism in HE: European Language Policy and Planning

Multilingualism in HE—the Council of Europe Perspective:
Intercultural Dialogue, Democratic Citizenship, Multiperspectivity,
and the Role of English

The work of the Council of Europe in the field of higher education and research focuses on issues related to the recognition of qualifications, public responsibility for higher education and research, higher education governance, citizenship and culture, and the social dimension of higher education (for more details go to www.coe.int/t/dg4/highereducation/).

The Council of Europe and the European Union share the aims of preserving linguistic and cultural diversity in Europe and promoting learning and use of languages as a means to support intercultural dialogue, social cohesion, and democratic citizenship, and as an important economic asset in a modern knowledge-based society. The Council of Europe’s efforts in this respect are best illustrated by the development of such policy instruments as the Common European framework of reference for languages (Council of Europe, 2001a)

and the recent recommendation on the use of the CEFR and the promotion of plurilingualism (Council of Europe, 2008), and such accompanying tools as the European Language Portfolio (ELP).

It is the Council of Europe's position that in a world in which international contacts, cooperation, and competition are the norm rather than exception, an understanding of other cultures and a sensitivity to their concerns and values are essential. The internationalization of higher education should help raise awareness among graduates of the fact that the impact of a statement is determined not only by what is said or written but also by the way in which it is conveyed. Intercultural dialogue and democratic citizenship require both a set of competences to communicate with others, to listen as well as to speak, to accept that other points of view may be as valid as one's own, and the ability to analyze issues from different points of view—multi-perspectivity (Council of Europe, 2001b). Higher education must educate the whole person and this cannot be done without opening the horizon of each individual to the world that lies beyond our immediate neighborhood.

Intercultural dialogue must be founded on a firm and well reflected set of values as well as on a willingness to consider the values of others and to reassess one's own convictions in the light of new and convincing evidence. Dialogue presupposes openness of mind in all partners, including the capacity to look at their own values and frame of reference with critical distance. These are also essential values and characteristics of higher education. (CDESR, 2006)

Higher education cannot fulfill its role unless it internationalizes and unless it opts for internationalization based on coherent values and policies (Council of Europe, 2009). Higher education graduates will require what the Council of Europe, in cooperation with the US Steering Committee of the International Consortium for Higher Education, Civic Responsibility, and Democracy, has termed "converging competences" (for details and forthcoming publications see www.coe.int/t/dg4/highereducation/Forum7_Converging_competences/).

Multi-perspectivity is conditioned by knowledge of languages. It is obvious that we cannot all learn all languages and English now has a strong position as an international lingua franca. Offering higher education courses only in English has a number of practical advantages, including the fact that it is the language of instruction most likely to be understood both by local and foreign students, and there is an increasing trend toward the use of English at the expense of almost all other foreign languages and sometimes also at the expense of local languages. The development toward broad use of English as not only *a* but *the* lingua franca does, however, also raise some problematic issues. They may perhaps best be described by the saying that whoever knows only his mother's tongue is limited to his mother's world. Without in any way wanting to diminish the importance of translations, knowing a number of foreign languages opens multiple perspectives that no translation can do. So the debate is not so much about whether to use English as a lingua franca or not but rather to what extent it should be used and what the place of local and national languages should be as languages of instruction and what place there should be for foreign languages other than English (for a discussion see Bergan, 2002).

Multilingualism Policies of the European Union: Promoting Language Learning and Linguistic Diversity

Today's European societies are facing rapid change due to globalization, internationalization, and technological advances. The increasing mobility of Europeans—currently 10 million people in the EU work in other member states—is an important sign of this change. The

4 MULTILINGUALISM AND HIGHER EDUCATION

EU has now 500 million citizens, 27 member states, 3 alphabets, and 23 EU official languages, some of them with a worldwide coverage. Some 60 other languages are also part of the EU heritage and are spoken in specific regions or by specific groups. Immigrants have brought a wide range of languages with them: it is estimated that at least 175 nationalities are now living within the EU's borders (EC, 2008b).

In its initial action plan on promoting language learning and linguistic diversity (EC, 2003) the European Commission stated that language skills play a key role in ensuring the social, cultural, and economic integration of Europe. Publishing the strategy for multilingualism (EC, 2005) the Commission reaffirmed the value of linguistic diversity and revealed the need for a broader policy to promote multilingualism. Among the proposals put forward by a group of intellectuals for intercultural dialogue set up at the initiative of the EC a suggestion was made that, beside mother tongue, citizens can choose a language of communication and a "personal adoptive language" depending on their needs, interests, and family background (EC, 2007). The role played by languages in business was the subject of another expert paper (EC, 2008c). In the Council of the European Union Resolution on a European strategy for multilingualism (EU, 2008) the member states have been requested to:

- promote multilingualism with a view to strengthening social cohesion, intercultural dialogue, and European construction;
- strengthen lifelong language learning;
- better promote multilingualism as a factor in the European economy's competitiveness and people's mobility and employability;
- promote the linguistic diversity and intercultural dialogue by stepping up assistance for translation;
- promote EU languages across the world.

In another document published in 2008 multilingualism is called an asset for Europe and a shared commitment (EC, 2008a). In a "Green Paper" presented that year migration and mobility are discussed as challenges and opportunities for EU education systems (EC, 2008c).

Multilingualism and the Bologna Process

In 1999, the Ministers in charge of higher education from 29 European countries agreed to introduce a set of reforms in their national higher education systems with a view to setting up a European higher education area (EHEA). This Bologna declaration set in motion a series of actions to make European higher education more compatible and comparable, more competitive, and more attractive for Europe's citizens and for students and scholars from other continents. The Bologna process is driven by the 46 countries participating in it in cooperation with a number of international organizations, including the Council of Europe. It aims at reorganizing higher education systems in European countries in such a way that:

- it is easy to move from one country to the other (within the EHEA)—for the purpose of further study or employment;
- the attractiveness of European higher education is increased so many people from non-European countries also come to study, work, or both in Europe;
- the EHEA provides Europe with a broad, high quality, and advanced knowledge base, and ensures the further development of Europe as a stable, peaceful, and tolerant community.

Student and staff mobility constitutes an overarching goal of the Bologna Process with a target set at the level of 20% of graduates that should have experienced a study or training period abroad by 2020. The Erasmus mobility program, launched in 1987, has grown from 3,000 students in 1987 to over 182,000 in 2007. Over 2 million students have studied abroad since 1987 and the objective is to achieve a cumulative total of 3 million by 2012. Erasmus supported staff mobility has grown from 7,800 in 1997 to over 33,000 in 2007 (EU, 2010, p. 12). These brief stays abroad of one or two weeks allow academics and other university staff to do short-term teaching assignments and maintain personal contact with colleagues at partner institutions (for more details go to http://ec.europa.eu/education/higher-education/doc1290_en.htm).

The issue of languages is of direct relevance to a number of core objectives of the Bologna Process. These include the promotion of mobility, of the European dimension of higher education, and of graduates' employability on the European labor market, as well as enhancing the attractiveness of European higher education. These objectives can only be achieved if all students irrespective of their specialization, especially students at undergraduate level, are given the opportunity to learn languages, and if mobile students receive adequate linguistic support.

Multilingualism in HE Programs: An Overview

The pattern of university language teaching is changing in an increasingly globalized higher education market. The recognition that language skills as an addition to a professional degree bring real employability advantages should ensure the continuing success of language centers in delivering language skills to both specialists and nonspecialists. According to Coleman (2004), the employment advantages of "a good degree from a good university" will ensure the survival of a few specialist modern language departments, where top researchers continue to focus on literature while their students are taught a different and less demanding curriculum by teaching fellows and postgraduate students.

Until fairly recently, language study in higher education was essentially the domain of language specialists, either in terms of philological, literary studies, or with respect to more practical tasks such as translation and interpretation. In recent years, a growing number of HE institutions have adopted policies designed to promote language learning. It is thus possible to speak of the emergence of the concept of HE education policy as asset of strategic decisions to equip students, researchers, and both academic and administrative staff with communicative skills in one or more foreign languages (see Tudor, 2008, for a sample of language policy models).

The rationale for integrating language learning fully into HE programs is based on three pillars:

1. Employability: knowledge of languages plays an important role in the employability of graduates in the increasingly mobile and multilingual global workplace.
2. Mobility: language competences are needed to take advantage of the possibilities for mobility.
3. The demands of the knowledge-based economy: graduates preparing themselves for the global workplace need to develop multilingual communication skills in parallel with their mainstream academic and professional training.

Globalization is placing greater linguistic demands on higher education worldwide. In Europe today, there is a desire to improve language-learning opportunities for all people to enhance European cohesion and competitiveness. In Asia, interest in improving lingua

franca languages such as Mandarin Chinese and English is on the rise. Globalization has made the world interconnected in ways not seen before. In an integrated world, integrated learning is increasingly viewed as a modern form of educational delivery. Promising solutions offer the content and language integrated (CLIL) approaches that involve using a language that is not a student's native language as a medium of instruction and learning for academic subjects. This also calls on content teachers to support the learning of those parts of language competences that students need to master the content (see Mehisto, Marsh, & Frigols, 2008, for an overview).

Teachers play a central role in the implementation of the new concept of plurilingual education. It is therefore crucially important that those who teach languages receive education and training that will equip them to carry out this task (for innovative proposals see Kelly & Grenfell, 2007; Newby et al., 2007).

The issue of professionalization in relation to the development of institutional multilingualism and individual plurilingualism requires a change of perspective. The Multilingual Universities Network of about 30 bi- or multilingual institutions of higher education worldwide recommends replacing the figure of a non-native speaker or learner, trying to bridge the gap to the native speaker, by the more complete figure of the learner as a social actor. Under this concept, the plurilingual social actor is not only learning languages in the classroom but also by using languages and different knowledge repertoires at his/her disposal in a variety of contexts (scientific, technical, administrative, and so on) in which s/he is acting (for details go to <http://multilingualuniversities.net/>).

The Bilingual University

In view of the accelerated processes related to globalization and internationalization, the idea of the bilingual university gains a new dimension. In 2000, the European Centre for Higher Education of UNESCO initiated a project directed at the analysis of the origins, mission, and functioning of the bilingual and multicultural university. Seven such institutions were analyzed—University of Ottawa, Canada; Åbo Akademi University, Finland; European University Viadrina, Germany; Free University of Bozen/Bolzano, Italy; University of Puerto Rico, Puerto Rico; University of Friburg, Switzerland; Babes-Bolyai University of Cluj-Napoca, Romania—and five key factors identified for their mission:

1. promoting the participation of a given linguistic minority group in the life of the country, region, or city;
2. promoting the coherence of a city, region or country, often in situations where few other institutions bridge the linguistic and sometimes cultural gaps between different populations;
3. promoting a wider outlook for the university and its graduates;
4. promoting bilingualism as an objective, not a condition;
5. encouraging students to stay in the region (Purser, 2000).

Research on Multilingualism in HE in Europe

Multilingual approaches in university education are subject of an extensive research work covering aspects reaching from institutional language policies, through learning and teaching in a multilingual environment, to assessment of the learning outcomes and socio- and psycholinguistic issues related to communication inside and outside the multilingual classroom. (For an overview see, for example, Wilkinson, 2004; Wilkinson, Zegers, & Leeuwen, 2006; Leeuwen & Wilkinson, 2007; Wilkinson & Zegers, 2007; Fortanet-Gómez & Räisänen, 2008; Wilkinson & Zegers, 2008; Veronesi & Nickenig, 2009.)

Multilingualism and Ideology

ADRIAN BLACKLEDGE

Language ideologies include the values, practices, and beliefs associated with language use by speakers, and the discourse which constructs values and beliefs at state, institutional, national, and global levels. Recently, studies of multilingualism in societies have drawn attention to the social positioning, partiality, contestability, instability, and mutability of the ways in which language uses and beliefs are linked to relations of power and political arrangements in societies (Gal & Woolard, 1995; Heller, 1995, 1999; Gal, 1998; Kroskrity, 1998; Woolard, 1998; Blommaert, 1999; Blackledge, 2005). Attitudes to, and beliefs about, language, are often not only about language. Gal and Woolard (1995) persuasively argue that ideologies that appear to be about language are often about political systems, while ideologies that seem to be about political theory are often implicitly about linguistic practices and beliefs. Debates about language are therefore not about language alone (Woolard, 1998), but are socially situated and tied to questions of identity and power in societies.

Language ideologies are positioned in, and subject to, their social, political, and historical contexts. Nor are language ideologies always fixed, stable, or immutable. They may be multiple, and influenced by changes at local, national, state, and global levels. Moreover, language ideologies are often contested, and become symbolic battlegrounds on which broader debates over race, state, and nation are played out. However, to say that language ideologies are contested and changeable over time is not to assert that they are necessarily always negotiable. There is often a dynamic tension between identities asserted and chosen by the self, and identities asserted and chosen for the individual by state, nation, or institution.

In public discourse language often becomes inseparably associated with a territorially bounded identity in a relationship that takes language, territory, and identity to be isomorphic (Freeland & Patrick, 2004). One implication of this is that ideally the nation should be monolingual, with adherence to another language often (mis)read as a lack of loyalty to the national identity. Claims to minority-language rights effectively challenge the very basis on which states are founded, in demanding the institutionalization of diversity. Nation-states are not founded on "objective" criteria, such as the possession of a single language. Rather, they have to be "imagined" as communities (Anderson, 1983; Billig, 1995). Billig (1995, p. 29) argues that the creation of a national hegemony often involves a hegemony of language. However, it is not sufficient to say that speakers of the same language belong to the same nation-state. This commonsense understanding of the relationship between language and nation ignores the diversity and variety of the language(s) spoken within many states. As Rampton's (1995) work has made clear, even the notion of a single "English" language is an oversimplification, as new varieties emerge from different cultural and social contexts.

While national identities can be negotiated in a variety of ways, current research privileges language and literacy policies as increasingly important means of social control which allow nation-states to define who is "in" and who is "out." Bourdieu argues that the official language is bound up with the state, both in its genesis and in its social uses: "It is in the process of state formation that the conditions are created for constitution of a unified linguistic market, dominated by the official language" (1991, p. 45). In order for one language to impose itself as the only legitimate one, the linguistic market has to be unified

2 MULTILINGUALISM AND IDEOLOGY

and the different languages (and dialects) of the people measured practically against the legitimate language:

Integration into a single “linguistic community”, which is a product of the political domination that is endlessly reproduced by institutions capable of imposing universal recognition of the dominant language, is the condition for the establishment of relations of linguistic domination. (Bourdieu, 1991, p. 46)

This linking of language, literacy, and national identity happens in a number of sites which include language planning, standardization, educational policy, citizenship testing, and language instruction for immigrants (Blackledge, 2005; Stevenson, 2006). Recent work on language testing for citizenship has demonstrated that in a broad range of national contexts particular languages and language varieties become gatekeeping devices to determine who is permitted to become a member of the community of citizens (Blackledge, 2005; Mar-Molinero, 2006; Maryns & Blommaert, 2006; Stevenson, 2006).

Another, related way to impose national identities is through educational policies that decide which languages are to be employed—and thus legitimized—in the public school system. Recent research has clearly documented the interpenetration of the ideological with the local, in institutional, nationalist, and political dimensions. When a language is symbolically linked to national identity, the bureaucratic nation-state faced with a multilingual population may exhibit “monolingualising tendencies” (Heller, 1995, p. 374).

May (2004, 2005) acknowledges poststructuralist research which proposes that for some individuals and groups language may not be a defining feature of identity, but argues that for others it may indeed be a salient feature. If identities are now theorized as multiple, hybrid, and contingent, languages nevertheless are clearly important features of identity claims for some individuals and groups. If the loss of a particular language is not necessarily the end of the world for a particular ethnic identity, for some individuals and groups language certainly *is* a key ideological battleground in the assertion of identities. May (2005, p. 330) points out that “particular languages clearly *are* for many people an important and constitutive factor of their individual, and at times, collective identities,” and argues elsewhere (2004, p. 43) that, while theoretically language may be just one of many markers of identity, in practice it is much more than that, as “the link between language and identity encompasses both significant cultural and political dimensions.” Identities are inevitably mediated in and through languages, which (whether we like it or not) come to be associated with particular ethnic or national characteristics. Of course some languages and language varieties are important for speakers’ identities without national or ethnic associations.

This entry has argued that in many Western countries a dominant ideology is constantly produced and reproduced which positions the majority language (usually English) as the only language of communication in institutional and other public contexts. Minority languages associated with immigrant groups are, as Bourdieu put it, rejected into indignity (1998, p. 46). Minority languages which have historically been associated with particular ethnic identities often continue to be important for particular groups (May, 2004), but have little capital in majority-language markets. Very often, multilingual societies which apparently tolerate or promote heterogeneity in fact undervalue or appear to ignore the linguistic diversity of their populace. An apparently liberal orientation to equality of opportunity for all may mask an ideological drive toward homogeneity, a drive which potentially marginalizes or excludes those who either refuse, or are unwilling, to conform.

Gal (2006, p. 15) argues that in powerful discourse monolingualism is often taken to be the natural state of human life. Furthermore, named languages are taken to be homogeneous, and to be expressions of the distinct spirit of a particular group. In this sense, where

linguistic practices conform to certain norms and standards, they are effective in legitimating political arrangements. However, Gal also points out that in Europe a new elite of multilingual speakers (of, e.g., French, German, and English) sustains a breadth of linguistic repertoires which transcends national boundaries. For such groups ethnolinguistic identity may be only an occasional issue. For multilingual speakers of languages with lower status, however, language issues may still be salient as people attempt to negotiate identities, often from relatively powerless positions.

As suggested earlier, however, language ideologies are neither simple nor monolithic. Notwithstanding the argument that minority-language speakers are subject to the symbolic violence of the dominant language ideology, some speakers who (or whose families) may traditionally have been associated with minority “ethnic” languages are using language and languages in new ways (Rampton, 1995, 1999). While some speakers are either unable to negotiate their identities from inextricably powerless positions, and others in powerful positions have no need to do so, some speakers in modern nation-states are using their sophisticated linguistic skills to negotiate new subject positions. In what Gal (2006, p. 27) describes as “self-conscious, anti-standardizing moves,” such negotiations may include linguistic practices which reframe previous standard varieties, incorporating, *inter alia*, urban popular cultural forms, minority linguistic forms, hybridities, and inventions. Here language practices associated with immigrant groups no longer represent backward-looking traditions, but may be linked to global youth culture and urban sophistication. Languages and language practices are not necessarily equated to national identity (but may be so), and are not necessarily dominated by the standardized variety. Despite powerful ideologies of homogeneity, populations in many countries—especially countries with a history of recent immigration—continue to be heterogeneous in their practices. May (2005) proposes that linguistic identities need not be oppositional, and asks “what exactly is wrong with linguistic complementarity?” (p. 337). May calls for further ethnographic studies which articulate and exemplify the broad linguistic principles of language-ideological research in complex multilingual contexts. An example of such work is the recent and ongoing research (Blackledge & Creese, 2010) which provides illustrative accounts of the complementarity of languages in “complementary schools” in urban Britain.

Stevenson and Mar-Molinero (2006) call for more critical examination of language policies which emerge from and contribute to the contradictions between monolingual ideologies and multilingual practices. In discussing language ideologies in contexts of modernity which include transnationalism and mass immigration, there is certainly a need for such rigor. At the same time, further studies are required which critically analyze the complexity and diversity of the multilingual practices of children, young people, and teachers in and out of educational settings, and of their attitudes, values, and beliefs about language. Through such studies we can come to a more comprehensive understanding of the complex relationship of languages to each other, to the speakers of those languages, and to the social structures in the society in which the languages are spoken.

Multilingualism and Language Rights

STEPHEN MAY

The growing presence of language rights (LR) in the disciplines of applied linguistics and sociolinguistics can be attributed to four distinct, albeit closely interrelated, academic movements. The first of these is the language ecology (LE) movement, charting the links between linguistics and ecology and situating the current exponential loss of many of the world's languages within a wider ecological framework. A second is the linguistic human rights (LHR) movement that argues, often on the basis of LE premises, for the greater institutional protection and support of minority languages within both national and supra-national contexts. These arguments are also echoed in a third domain of academic legal discourse that has developed with respect to minority group rights generally, but with an increasing focus on the specific implementation of minority language rights (MLR) in national and international law. A fourth, increasingly influential, position has seen a deliberate move away from the biological/ecological analysis of LE, and some LHR arguments, to a more overtly critical sociohistorical/sociopolitical analysis of language rights.

While these various positions are by no means uniform, they do share broadly five key concerns. The first concern has to do with the exponential decline and loss of many of the world's languages. Indeed, of the estimated 6,900 languages spoken in the world today, it is predicted on present trends that the vast majority (up to 90%) may die by the end of the 21st century (Krauss, 1992). Language decline and loss occur most often in bilingual or multilingual contexts in which a majority language—that is, a language with greater political power, privilege, and social prestige—comes to replace the range and functions of a minority language. The inevitable result is that speakers of the minority language “shift” over time to speaking the majority language.

Of course, such language loss and language shift have always occurred—but never to this extent and never before at such an exponential rate. The potential scale and rapidity of language loss predicted here also highlights the inevitable social, economic, and political *consequences* for minority language speakers of such shift and loss. We can see this clearly if we consider which groups are most affected by language loss—almost always minority groups which are (already) socially and politically either marginalized or subordinated. Moreover, linguistic dislocation for a particular community of speakers seldom, if ever, occurs in isolation from sociocultural and socioeconomic dislocation as well.

The second principal concern has to do with the reasons why certain languages, and their speakers, come to be “minoritized” in the first place. Advocates of LR argue that the establishment of majority/minority language hierarchies is neither a natural process nor primarily even a linguistic one. Rather, it is a historically, socially, and politically *constructed* process (May, 2012), and one that is deeply imbued in wider (unequal) power relations. Following from this, if languages, and the status attached to them, are the product of wider historical, social, and political forces, there is, in turn, nothing “natural” about the status and prestige attributed to particular majority languages and, conversely, the stigma that is often attached to minority languages, or to dialects.

In short, languages are “created” out of the politics of state-making, not—as we often assume—the other way around. This is, in turn, a result of the pervasive influence of political nationalism over the last three centuries and the linguistically homogeneous state that is its product. In short, nationalism has promoted the idea that a single, common

"national" language (sometimes, albeit rarely, a number of national languages) is the only valid basis of modern social and political organization. The process of selecting and establishing a common national language has usually involved two key aspects: *legitimation* and *institutionalization* (Nelde, Strubell, & Williams, 1996; May, 2012). Legitimation is understood to mean here the formal recognition accorded to the language by the nation-state—usually, via "official" language status. Institutionalization, perhaps the more important dimension, refers to the process by which the language comes to be accepted, or "taken for granted" in a wide range of social, cultural, and linguistic domains or contexts, both formal and informal. Both elements, in combination, achieved not only the central requirement of nation-states—cultural and linguistic homogeneity—but also the allied and, seemingly, necessary banishment of "minority" languages and dialects to the private domain.

Proponents of language rights for minority groups argue that the emphasis on cultural and linguistic homogeneity within nation-states, and the attendant hierarchizing of languages, are thus neither inevitable nor inviolate—particularly in light of the historical recency of nation-states, and the related, often arbitrary and contrived, processes by which particular languages have been accorded "national" or "minority" status respectively. These arguments about the historical and geopolitical situatedness of national languages also apply at the supranational level. As with the construction of national languages, the ascendancy of English as the current world language is also invariably linked with modernity and modernization and the associated benefits that accrue to those who speak it. The usual corollary to this position is that the social mobility of the minority language speaker will be further enhanced if they *dispense* with any other (minority) languages.

A third principal concern of language rights' proponents is to critique the principle of "language replacement" that centrally underlies the social and political processes just outlined—that one should/must learn these languages *at the expense of* one's first language(s). Consequently, the promotion of cultural and linguistic homogeneity at the collective/public level has come to be associated with, and expressed by, individual monolingualism. This, in turn, has led to educational approaches that specifically exclude first languages from the teaching and learning process and, more broadly, construct student bi-/multilingualism in "subtractive" rather than "additive" terms (May, 2003). Central to these language replacement arguments is the idea that the individual social mobility of minority language speakers will be enhanced as a result. Relatedly, LR advocates are consistently criticized for consigning, or ghettoizing minority language communities within the confines of a language that does not have a wider use, thus actively constraining their social mobility (see, e.g., Barry, 2001).

These arguments appear to be highly persuasive, at least at first glance. In response, however, LR proponents argue that the presumptions and assumptions that equate linguistic mobility *solely* with majority languages are themselves extremely problematic. For a start, this position separates the instrumental and identity aspects of language. On this view, minority languages may be important for identity but have no instrumental value, while majority languages are construed as primarily instrumental with little or no identity value. However, it is clear that *all* languages embody and accomplish both identity and instrumental functions for those who speak them. Where particular languages—especially majority/minority languages—differ is in the *degree* to which they can accomplish each of these functions, and this in turn is dependent on the social and political (not linguistic) constraints in which they operate (May, 2003, 2005a). Thus, in the case of minority languages, their instrumental value is often constrained by wider social and political processes that have resulted in the privileging of other language varieties in the public realm. Meanwhile, for majority languages, the identity characteristics of the language *are* clearly important for their speakers, but often become subsumed within and normalized by the instrumental functions that these languages fulfill.

On this basis, LR advocates argue that the limited instrumentality of particular minority languages at any given time need not always remain so. Indeed, if the minority position of a language is the specific product of wider historical and contemporary social and political relationships, changing these wider relationships positively with respect to a minority language should bring about both enhanced instrumentality for the language in question, and increased mobility for its speakers. We can see this occurring currently, for example, in Wales and Catalonia, with the emergence of these formerly subjugated languages into the public domain—particularly via, but by no means limited to education. Likewise, when majority language speakers are made to realize that their own languages fulfill important identity functions for them, both as individuals and as a group, they may be slightly more reluctant to require minority language speakers to dispense with theirs.

And this brings us to the fourth principal concern of language rights' proponents—the legal protections that can potentially be developed in order to enhance the mobility of minority language speakers while at the same time protecting their right to continue to speak a minority language, *if they so choose*. It is here that the influence of the linguistic human rights (LHR) movement, championed by Tove Skutnabb-Kangas, is most prominent. The LHR research paradigm argues that minority languages, and their speakers, should be accorded at least some of the protections and institutional support that majority languages already enjoy (see, e.g., Kontra, Skutnabb-Kangas, Phillipson, & Várady, 1999; Skutnabb-Kangas, 2000). The key position here is that minority languages should not just enjoy what Kloss (1977) terms “tolerance oriented rights”—that is, the right to use one's language unmolested in the private domain—a right attributable to all groups. Rather, certain minority languages should also be afforded “promotion-oriented rights”—that is, the right to use a minority language in the public domain—either where these languages are associated historically with a particular area, or where sufficient numbers warrant.

Comparable arguments in international law provide an additional basis on which these judgments can be made in any given context (see, e.g., de Varennes, 1996; Henrard, 2000). A central distinction in both discourses is one made between national minority groups and indigenous peoples on the one hand and ethnic minority groups on the other. The former may be regarded as groups that are historically associated with a particular territory but because of conquest, confederation, or colonization are now regarded as minorities within that territory. The latter may be regarded as voluntary migrants and (involuntary) refugees living in a new national context (see Kymlicka, 1995 for further discussion).

Three key tenets of international law can be applied to the further development of language rights in relation to these two broad minority groupings. The first principle, which is widely accepted, is that it is not unreasonable to expect from national members some knowledge of the common public language(s) of the state. This is, of course, the central tenet underpinning the current public linguistic homogeneity of modern nation-states. However, LR advocates assert that it is also possible to argue, on this basis, for the legitimation and institutionalization of the languages of national minorities within nation-states, according to them at least some of the benefits that national languages currently enjoy. LR proponents qualify this by making it clear that the advocacy of such minority language rights is *not* the language replacement ideology in reverse—of replacing a majority language with a minority one. Rather, it is about questioning and contesting why the promotion of a majority (national) language should necessarily be *at the expense* of all others.

A second principle is that in order to avoid language discrimination, it is important that where there is a sufficient number of other language speakers, these speakers should be allowed to use that language as part of the exercise of their individual rights as citizens. That is, they should have the *opportunity* to use their first language if they so choose. Again, this principle can clearly be applied to minority language speakers within particular nation-states. The third principle arises directly from the previous one—how to determine exactly

what is “appropriate and reasonable” with regard to individual language preferences. Following the prominent political theorist, Will Kymlicka (1995), May (2012) has argued, for example, that only national minorities can demand *as of right* formal inclusion of their languages and cultures in the civic realm. However, this need not and should not preclude other ethnic minorities from being allowed *at the very least* to cultivate and pursue unhindered their own historic cultural and linguistic practices in the private domain. In other words, distinguishing between the rights of national and ethnic minorities still affords the latter far greater linguistic protection than many such groups currently enjoy.

The final concern of the language rights paradigm—most prominent in more recent work in the area (see the collections by Patrick & Freeland, 2004, and May, 2005b)—addresses directly the question of how to recognize language rights, while at the same time avoid essentializing the languages, and their speakers, to which these rights might apply. This difficult balancing act necessarily involves rejecting the “essentialist tendency,” closely allied with an often-deterministic account of the links between language, identity, and the wider ecological system, that is most evident in arguments for LE, as well as in those LHR arguments that are predicated on LE principles (e.g., in the work of Skutnabb-Kangas, 2000). Such arguments assume—in their less sophisticated manifestations, explicitly, and even in their most sophisticated forms, at least implicitly—an almost ineluctable connection between language and (ethnic) identity. And yet, this position stands in marked contrast to the widespread consensus in social and political theory, and increasingly in sociolinguistics and critical applied linguistics, that language is at most only a contingent factor of one’s identity. In other words, language does not define us, and may not be an important feature, or indeed even a necessary one, in the construction of our identities, whether at the individual or collective levels (see, e.g., Edwards, 1994; Brutt-Griffler, 2002). This critique on the detachability of language is complemented by a wider constructivist consensus within social theory of the merits of hybridity—that our social, political, and linguistic identities are inevitably plural, complex, and contingent (see, e.g., Makoni & Pennycook, 2007).

Clearly then, an acceptance of the contingent nature of the language-identity link, and the wider principle of hybridity, is a necessary prerequisite before work in language rights can continue to develop further theoretically. But there is also a key weakness in constructivist accounts of language—their failure to address adequately the central question of why, *despite* the clear presence of hybrid linguistic identities, historically associated languages continue often to hold considerable purchase for members of particular cultural or ethnic groups in their identity claims. To say that language is not an inevitable feature of identity is thus *not* the same as saying it is unimportant. Yet many constructivist commentators in (rightly) assuming the former position have also (wrongly) assumed the latter. In other words, they assume that because language is merely a contingent factor of identity it cannot therefore (ever) be a *significant* or *constitutive* factor of identity.

This position is extremely problematic, not least because of the considerable evidence that suggests that, while language may not be a *determining* feature of ethnic identity in many geo- and sociopolitical contexts in the world today, it remains nonetheless a *significant* one in many instances, particularly in many historical and contemporary political conflicts (see, e.g., Blommaert, 1999; Blackledge, 2008; May, 2012). As Adrian Blackledge observes

We can hardly argue theoretically that for students who died protesting the right to establish Bengali as the national language of East Pakistan in 1952, language was not a key feature of identity. There are of course many other examples in present-day Europe. (2008, p. 33)

In these conflicts, particular languages clearly *are* for many people an important and constitutive factor of their individual, and at times, collective identities. This is so, *even* when holding onto such languages has specific negative social and political consequences for their speakers, most often via either active discrimination, or oppression.

In theory then, language may well be just one of many markers of identity. In practice, it is often much more than that. Indeed, this should not surprise us since the link between language and identity encompasses both significant cultural and political dimensions. The cultural dimension is demonstrated by the fact that one's individual and social identities, and their complex interconnections, are inevitably mediated in and through particular languages. The political dimension is significant to the extent that those languages come to be formally (and informally) associated with particular ethnic and national identities. These interconnections also help to explain why, as Fishman (1997) argues, a "detached" scientific view of the link between language and identity may fail to capture the degree to which language is *experienced* as vital by those who speak it. It may also significantly understate the role that language plays in social organization and mobilization.

As for the ongoing concern over essentialism, this too can be addressed directly. Advocacy of LR does not *necessarily* entail an essentialized, static view of the language-identity link, or a homogenous conception of the wider linguistic group. As Will Kymlicka has argued in relation to minority rights more generally, advocates of such rights are rarely seeking to preserve their "authentic" culture if that means returning to cultural practices long past. If it were, it would soon meet widespread opposition from individual members. Rather, it is the right "to maintain one's membership in a distinct culture, and to continue developing that culture in the same (impure) way that the members of majority cultures are able to develop theirs" (1995, p. 105). Cultural change, adaptation, and interaction are entirely consistent with such a position. The crucial difference, however, is that members of the minority are themselves able to retain a significant degree of control over the process—something which until now has largely been the preserve of majority group members. The key issue for minority language speakers thus becomes one of cultural and linguistic *autonomy* rather than one of retrenchment, isolationism, or stasis.

Adopting this view actually allows for the promotion of a far more pluralistic, open-ended interpretation of language and identity, recognizing the opportunity or potential for holding multiple, complementary cultural and linguistic identities at both individual and collective levels. Maintaining one's minority ethnically affiliated language—or a dominant language, for that matter—avoids "freezing" the development of particular languages in the roles they have historically occupied. Equally importantly, it questions and discards the requirement of either a singular, or replacement, approach to the issue of other linguistic identities, which has been the major historical legacy of nationalism and the nation-state system. And finally, such a view, of course, accords far more closely with the often-complex linguistic repertoires of individual multilingual speakers themselves. This multilingualism has tended until now to be sanctioned (only) in the private, familial, or community realm but, as LR proponents argue, there is no reason why such multilingualism could not be extended to the public, or civic, realm as well.

Multilingualism in Legal Contexts

XABIER ARZOZ

Law is the most linguistic of social institutions. It cannot exist outside language: It is drafted, approved, proclaimed, administered, interpreted, and repealed through acts of language. In a number of countries law is proclaimed or administered in more than one language. The bilingual or multilingual nature of law as a social institution raises specific issues and difficulties, as well as general issues flowing from applied linguistics (Gibbons, 2004; Mattila, 2006). This entry will discuss various issues arising from *national* legal contexts when there is more than one official language, or when more than one language is recognized to some extent. Apart from states, *supranational* and *international* institutions also have to deal with the challenges posed by multilingualism (Tabory, 1980; Paqué, 1997). In particular, multilingualism is posing serious challenges to the European Union, a supranational organization that operates in more than 20 languages (Schübel-Pfister, 2004; Müller & Burr, 2004; Pozzo & Jacometti, 2006; Arzoz, 2008; Derlén, 2009).

Multilingualism and the Constitution

The constitutions of 173 states of the world include some language-related provisions. Most of them, however, give recognized rights or status to one language only. Some constitutions do recognize multilingualism existing within state borders but approaches in this regard may differ considerably.

First, constitutions may proclaim a number of languages as state, official, or national languages (e.g., Belgium, Canada, Finland, South Africa, Switzerland, India). There is no commonly accepted definition of the notion of official status. The notion always implies a symbolic recognition, and normally also involves in practice access to education in the relevant language and the use of it within the framework of certain authorities. Beyond that, a variety of legal arrangements from state to state can be connected to an official status. Therefore, official multilingualism can be very comprehensive in scope or limited to certain functional areas (e.g., education) or territorial areas (e.g., at the local or substate level). In federal or quasi-federal states, the power to regulate the official status and the protection of a language at the regional level may be devolved to substate authorities.

Official bilingualism or multilingualism does not mean that all languages are treated equally. The number of official languages is both a political and a distributive decision. The Canadian and Finnish Constitutions give equal status to English and French and to Finnish and Swedish, respectively, but they provide a much weaker status to languages spoken by indigenous peoples. Even South Africa, whose Constitution appears to be specially generous in this regard, had to limit the recognition of official status to 11 languages (Afrikaans, English, plus nine indigenous languages).

A second legal approach that is widely used is the recognition of specific rights to the members of linguistic minorities. A significant number of modern East and Central European Constitutions recognize some positive language rights on behalf of autochthonous linguistic minorities (also called “national minorities”).

In general terms, the proclamation of official status itself does not lead to immediate legal effects, although it can be the basis for recognition of language rights through legislation. On the basis of constitutional principles and international law, the most complete realization of the protection of linguistic minorities should imply the development and implementation of a full set of language rights in different public domains, as long as the number of users of those rights justify them. According to their discretion, states can choose the form, timing, and methods in order to achieve this constitutional objective, both taking account of the existing social conditions and of the availability of organizational and financial resources for its implementation.

A third, more modest, legal approach consists of the acknowledgement of linguistic diversity or of the contribution of various languages to the cultural and linguistic richness or to the cultural heritage of society as a whole. Even these constitutional provisions are not legally irrelevant: They proclaim values that should unite the state's community and direct legislative action.

Multilingualism and Legislation

When the equal status of official languages is constitutionally entrenched, two (or more) language versions of the same statutory text are signed by the relevant authority and published in the corresponding official statute book and all those versions are equally authentic.

There are several legal techniques for drafting bilingual or multilingual legislation. The classical one is to present in Parliament a draft in one language and, when the text is definitively passed, translate it, either before or after enactment. In theory, equality of status should also imply that all official languages are equally considered and used through the legislative process. Specially in Canada, different possibilities in this regard have been either theoretically explored or practically tested (Revell, 1998). Basically, legal drafters and translators from all official languages should be involved at all stages of the drafting process.

The most ambitious technique of drafting bilingual legislation is codrafting, since it accords each language and culture parity of esteem: The text is simultaneously drafted and coordinated by two (or more) people, provision by provision, in the two (or more) official languages at all stages of the drafting process. Finally, the two (or more) legal versions of the same legal text should be read and passed by Parliament.

However, even in officially bilingual countries the codrafting principle is not fully observed and much more asymmetrical schemes are adopted in reality. For instance, according to the Finnish constitution, law proposals and their explanatory reports must be presented by the Government to Parliament in both Finnish and Swedish. But there is no constitutional provision imposing the reading of the Swedish text, and only the Finnish language texts of proposed laws are read in committees and plenary sessions of Parliament. Therefore, the Swedish text of a Finnish law is never subject to any discussion during the legislative work of Parliament but it is formulated by officials only. Although it is a translation, it is equally authentic once the law is enacted and comes into force. These are more or less the circumstances prevailing in most bilingual or multilingual countries or substate entities.

The translation of statutes, either imposed by constitutional order or by international obligations (such as the European Charter for Regional or Minority Languages, Article 9[3]), or provided by authorities for convenience or information, is a typical institutional practice of multilingual legal contexts. Procedures of translation and revision must be organized conveniently: Legal experts as well as translators need to be involved.

In some countries, much care is taken not only with regard to the quality of the translation itself, but also to the preservation of terminology of the nondominant language. In

Finland Swedish legal language has to be preserved as close as possible to the Swedish legal terminology of Sweden (Koivu & Mattila, 2006, p. 29). In the Italian autonomous province of South Tyrol an official committee establishes legal terminology and ensures that the German legal language in South Tyrol does not vary from the German legal terminology of Austria (Palermo & Pförtl, 1997).

Legal translation is easier when it is made within one and the same legal system, as is the case in most national contexts. In Canada, however, the two official languages express two different legal traditions, common and civil law. Legal drafters, translators, and interpreters in that country must not only master two languages but also the intricacies of two different legal cultures (Sullivan, 2004).

Even if one text is the original and the other a translation of it, equality of status implies generally that both are to be considered equally authentic statutory texts. When the content of a statute seems to be unclear, it should be read in both authentic texts. Sometimes, one language will make clear what the other leaves ambiguous. This is one of the recognized advantages of official multilingual legislation (Morris, 1999, p. 79; Koivu & Mattila, 2006, p. 33). When, however, the wording of the two (or more) language versions clearly point in different directions, the principle of equal status prevents giving prevalence to one language. Differences in meaning have to be eliminated by ordinary methods of legal interpretation: This, in practice, can lead to adopting the meaning expressed by one of the language versions, very likely the one read in Parliament.

In some jurisdictions there are explicit rules which bestow constitutional or legislative precedence upon one of its languages, usually for political reasons: For instance, the Irish (Gaelic) version of the Constitution in Ireland and the Chinese version of statutes in Hong Kong are given precedence over the English version. This seemingly expedient way to solve contradictions is not without difficulties: A court should *prima facie* be bound to determine whether, as regards the versions of the relevant law, conflict exists between the predominant language and the other(s). By contrast, when there is no legislative precedence, no criterion such as conflict has to be satisfied before one looks to the other language text for interpretative assistance (Morris, 1999, p. 79).

A specific legal source tends to be multilingual, regardless of the monolingual or multilingual character of the state: International treaties can be ratified by contracting parties in more than one linguistic version. According to Article 33 of the Vienna Convention of the Law of Treaties, when a treaty has been authenticated in two or more languages, the text is equally authoritative in each language, unless the treaty provides or the parties agree, that in case of divergence, a particular text shall prevail. The terms of a treaty that has been authenticated in two or more languages are presumed to have the same meaning in each authentic text, and differences of meaning must be removed by looking for the meaning which best reconciles the texts, having regard to the object and purpose of the treaty.

Multilingualism and the Courts

Access to justice in a recognized language (either an official or minority language) is one of the most relevant but also delicate of language rights. This right not only concerns individuals, but the entire justice system. Often, the right is proclaimed on paper but there is no accessibility to justice in a real and meaningful way for the speakers of nondominant official languages.

There are significant consequences that emanate from the constitutional or legal right of access to justice in more than one official language (Bloom, 2006, p. 434). The first consequence, obviously, deals with members of the public. The judicial process starts with an understanding of one's rights and recurses through the availability of all statutory legislation and accompanying regulations in the recognized languages, and continues with the

availability of counsel who can communicate easily in the relevant languages. Added to this is the freedom to have proceedings drafted in those languages; the ability to present one's case before the courts, both orally and in writing, in those languages; and the right to receive judgment or a translation in the preferred language. Second, members of the judiciary and other judicial staff (prosecutors, registrars, etc.) should be bilingual. In some countries (Finland, Switzerland, Belgium), there is a legal obligation for judges and other personnel to be bilingual, irrespective of whatever this means in practice.

It is uncommon for judicial systems to function bilingually outside the federal level, with perhaps the most striking exception being the courts of the Judicial District of Montréal in Canada (Bloom, 2006, p. 435), of the few bilingual or trilingual cantons of Switzerland (Papaux, 1999, p. 33) and, as of 1991, of South Tyrol in Italy (Palermo & Woelk, 2001). By contrast, regional courts of the officially bilingual region of Brussels in Belgium follow the dual justice system (i.e., separate courtrooms operating in either French or Flemish but not both).

As a consequence, in many bilingual or multilingual jurisdictions language services are offered basically in form of an interpreter. This policy is opposed by those that see it as a second-class treatment and a violation of equality, since speakers of the official non-dominant language must cope with longer delays and must often waive their right to use their preferred language.

Multilingualism and Media

HELEN KELLY-HOLMES AND SARI PIETIKÄINEN

Introduction

Multilingualism is a crucial part of media. Today's media environment is inevitably multilingual. Media are a site of multilingual practices, a place where we get information about multilingual communities and other languages, and about our own sociolinguistic environment; they are a site where we can see our own views and norms about multilingualism reflected or challenged; they are also a site for language learning and for multilingual innovations.

These various roles and processes mean that the relationship between multilingualism and media is a complex one. It is also one worthy of attention and research, as it opens up a window to examine and discuss several important processes, including language norms and ideologies, language policies, identity, and linguistic markets (see Spitulnik, 1998; Kelly-Holmes, Moriarty & Pietikäinen, 2009). In this entry, we first examine how mediation impacts on multilingualism; we then go on to look at how media can both limit and enhance multilingualism; and, finally, we briefly survey multilingual media practices.

Mediation and Multilingualism

There are of course myriad types of media, but what they all have in common is the aspect of mediation: They involve non-direct, non-face-to-face communication taking place through a technological and regulated system. In order for media communication to happen, some intervention or support (technical, financial, editorial, etc.) is needed. This mediation inevitably involves selection and decision-making processes about language(s): the decision to use one language rather than another; the decision to opt for a formal register or type of language; the decision to use a speaker who has a particular accent, and so on. This means that all media give shape to our experience of multilingualism, and they do so in part through this selectivity. Language relations and our understanding of multilingualism, understood not just as different languages (e.g., French, Arabic), but also as different dialects, accents, and ways of speaking, are transformed by the use of media and mediation technologies, which amplify or reduce multilingualism in various ways. Mediation necessitates organizing, selecting, and focusing our multilingual environment.

The selection and decision-making process in any media environment is complex. In the mass media in particular (newspapers, radio, television), it is often someone other than the direct language users who makes the decision. Such decisions may be made at an institutional level, and can be considered policy decisions (e.g., news policy, language policy). At the most basic level, the state "decides" which language its major national media should be in. In media environments which are more controlled from the top down, these decisions are made by a relatively small group of disproportionately powerful people, such as editors and owners of the media. Behind these decisions, however conscious or subconscious they may be, lie individual, group, and national language ideologies in relation to different languages, varieties, standards, multilingualism, and so on. Sometimes

language choices are also made to brand a media product for example as more local (e.g., through use of local dialect or regional accent), more mobile (e.g., through tokenistic use of English), or more authentic (e.g., through emblematic use of rap jargon or minoritized languages). This manifests in media texts, for example, as loanwords or shifts in style or genre. It is important to remember that each media space has its own internal hierarchy for linguistic resources and its own internal normative system for organizing the use of them.

In the contexts of globalization and technological innovations, media have been “democratized” (Zhao & Hackett, 2005): They have become cheaper to produce, more fragmented and more “bottom-up.” As a consequence, mediation of multilingualism is less subject to the gatekeeping mentioned above and has the potential to become closer to everyday language use. We can find numerous examples in computer-mediated communication of practices which seem much closer to everyday conversations and language use, even though they are mediated, for example instant messaging, chatting, blogs, and social-networking sites. However, these novel mediations still involve decisions about language(s), even if only made by one individual about how to mediate him/herself, and which form this should take. It seems clear that language policy and ideology are involved when the state is attempting to mediate itself and makes language choices on this basis. However, even where there are massive differences in terms of reach, scale, economics, or authority involved—for example in the difference between a national daily newspaper and a personal blog read by a handful of people—they still share the common phenomenon of mediation and decision making in terms of language(s).

Encouraging Monolingualism, Reducing Multilingualism

The reduction of multilingualism in media environments has its origins in the parallel development of national media and of the modern nation-state. A key project of the nation-state was to find a unifying, homogeneous culture and language, and national media played a major role in this development. Anderson (1991) argues that it was the widespread availability of media that led to national consciousness and, simultaneously, the establishment of national languages, tied with the ideology of a monolingual nation. Along with ideologies, there were also practical reasons for reducing multilingualism in media. In their early days, print and broadcast media were extremely costly and labor-intensive. For this reason, decisions had to be made about which language to use, as producing media in multiple languages was seen as simply not feasible. Particular national media had a firm territorial base, either because of their broadcasting range, or because of their hard-copy distribution (in pre-digital days), and this reinforced the idea of one language being linked to one group of people (a nation) who lived in a particular territory. Interestingly, the European Broadcasting Union still defines national broadcasters on the basis of territory—even in a digital age—and links language explicitly to territory. A newspaper or a common media product is still seen as a key way to mark, draw attention to, or rally individuals around a group, regional, linguistic, or ethnolinguistic identity (Busch, 2004).

Related to their role in the creation—imagined or otherwise—of modern nation-states, at least in the European context, media came to be seen as detrimental to multilingualism (see for instance Wright, 2000; Jaffe, 2006). As highlighted above, language ideological and political motivations were—and still are—facilitated by technological issues and limited resources. Decisions about language in the media have as much to do with other factors as they have to do with language. More often than not they have also to do with speakers, resources, ideologies, and power. And this in turn has everything to do with the perceived value and function of a particular language and its speakers.

The practices of European nation-states in relation to the creation of monolingual national media as part of the project of creating a unified and monolingual nation-state were largely copied by many newly independent, postcolonial countries, as pointed out by Ricento (2006) and others. For example in parts of Africa and Asia the decision was often made in favor of English as a “neutral” language in complex multilingual situations. Of course the choice of English is not neutral, and even the idea of describing it or rationalizing it as a “neutral” choice is a classic example of a language ideological process. The reasoning often used to justify this choice, apart from the “neutrality,” is the cost-effectiveness and accessibility. However, the use of English rather than other widespread lingua francas (e.g., Kiswahili) or multilingual combinations of local and regional languages has language ideological implications: It conveys an idea that these languages are somehow not fit for modern practices such as media (and education, etc.), and that multilingualism is divisive and incompatible with the national project that succeeds colonialism and which national media are intended to promote.

Another solution for the reduction and regulation of multilingualism was the development of parallel monolingualism in the media. For example, in Belgium and Switzerland, media are available equally (or more or less equally) in the various national or co-official languages. This, too, conveys a particular language ideological position: Languages are separate systems that should be treated equally but not mixed, even though people’s everyday practices in multilingual contexts are often mixed (see Androutsopoulos, 2006a). The homogenization of language use in national media went beyond multilingualism. The didactical aim of the national media materialized also in a construction of the “proper” way of speaking. This normative view resulted in the portrayal of a “media” speaker, with a “neutral” or “standard” way of speaking that is rare to find in real language communities. The notion of a “standard” or “media” speaker is best exemplified perhaps in the concept of “BBC English,” which would have been considered a standard to aspire to, even beyond media contexts, in its freedom from regional or class-based variation. While the situation has changed considerably, it is still worth looking at which resources are valued in media contexts (and which are not), and whose voices are present in contemporary media (and whose are not).

Facilitating and Expanding Multilingualism

As pointed out above, media play a central role in normalizing language use and imposing monolingual norms in many societies. For this reason, they have been seen as powerful institutions in reducing multilingualism. However, this perceived power to change people’s language behaviors, impose norms, and also alter language attitudes and ideologies has encouraged those who want to promote multilingualism, particularly in the form of promoting minoritized languages, to see mass media as a key focus of their objectives. Fishman (1991) developed a staged plan for reversing language shift (i.e., for moving from non-use or only limited and declining use of a language in certain domains, registers, or areas of life to full use of the particular language in all domains, registers, or areas). Of particular significance was the attainment of media in the relevant language, for a number of reasons. First of all, mass media can be seen as a high-status domain (along with education and the political sphere). They are also a key site of modern life. The dominant-language ideological logic is reversed here: If mass media in a dominant or majority language have caused people to shift or switch language, because they want to participate in this key site of modern life, then mass media in the minoritized language might cause them to change or shift back. Another argument is parity of esteem. Media represent a status area in that significant amounts of money are invested in them. At the time when Fishman was writing,

and at the time when television (and radio) began, nation-states were the main investors in broadcast media. Thus, the language choice by the state as reflected in national media sends a powerful message about the importance of particular languages. National media are costly. In technical terms, prior to the development of digital technology, they represented massive infrastructural investment. They still do today because, even though technical costs have reduced, quality programming still costs. Therefore the appearance of a minority language in a prestigious, high-cost domain of media should send a very powerful message about the status and importance of that language to its speakers and learners and to others as well. If the “imagined community” (Anderson, 1991) can be created by national television in a majority language, then perhaps the minority imagined community can also be created by minority-language media.

As well as trying to send messages about status, minority-language media are seen as a key way in which to maintain and develop a language. Media are a ubiquitous part of people’s everyday lives and a lot of language is experienced and also acquired through media. Therefore, if minority languages are left out of media, their linguistic resources, values, and functions are not “updated,” and they can be seen to stall in their development and change. Similarly, minority speakers will not have the vocabulary or a mediated forum to discuss what they have been experiencing, perhaps encouraging a further move to a majority language. Using media is seen as an important way of maintaining a language (reading, hearing, speaking, writing, etc.). For example, when TG4, the Irish-language television channel, began to broadcast the Wimbledon tennis tournament with Irish-language commentary, this was the first time that a sport like tennis had been covered in Irish in the media, and the channel had to develop a range of vocabulary in order to describe accurately what was going on (Moriarty, 2011). New media genres also often facilitate language innovations in minority-language contexts, such as hybridity and mixing (Pietikäinen, 2008). In terms of maintenance and development, minority-language media can therefore be seen to add substantially to the corpus development of a particular language, through development of new vocabulary, styles, registers, and genres that will keep the language “up-to-date” and thus, so the thinking goes, enable speakers to use it in a wider range of areas of their lives, thereby encouraging maintenance rather than shift or code switching in these areas.

Media can also function as informal language-learning contexts; they can help to normalize “messy” multilingual practices and appropriation of diverse linguistic resources and their use in the public arena. Particularly where there are limited opportunities to use a minority or immigrant language in everyday life, and perhaps even fewer to acquire it beyond formal learning opportunities, media are seen to provide a valuable forum where language learning and appropriation can happen. The American children’s television program *Sesame Street* is a good example here, enabling the learning of English and Spanish by preschool children. Again, following the national model, minority-language movements have sought to encourage learning and acquisition through media. Children’s television has been seen as a particular priority here because of the need to provide a forum for language learning and language use, and also in order to provide attractive offerings that can compete with programs in the majority language. For example a Sámi children’s television program, *Unna Junna*, uses several Sámi languages as spoken languages and the national languages of Swedish and Finnish in its subtitles.

The development of media in minority languages, together with globalization of media and fragmentation of production and consumption, has created new mediated linguistic spaces, which are often considered beneficial for multilingualism. These processes have led to niche markets for media products both in a particular language and in multilingual versions (e.g., gaming, advertising, blogging). This in turn has led to a new, albeit still limited, market for language-related media jobs, for example in Wales and Ireland. Creating

a job market for speakers of minority languages is another way in which media promote and encourage multilingualism.

Multilingual Practices in the Media

The context within which media are produced and consumed is always more or less multilingual. On the production side, the ways in which multilingualism is managed in media vary from “forced” monolingualism to unregulated, creative use of diverse linguistic resources. One typical type of multilingualism we see in media production is “parallel monolingualism” (Heller, 2006), which involves the provision of parallel texts in different languages. For example, the Catalan newspaper *El Periódico* is first written in Castilian/Spanish, before being completely machine-translated into Catalan. The two versions are sold side by side (in parallel with each other) and are identical in terms of content. Similarly, many corporate and commercial Web sites are now offered in parallel-language versions, particularly in situations where (some) languages are clearly delineated (officially) by territory (e.g., Belgium, Canada). Global media products in English have added to multilingualism in the form of bringing English into new domains and areas via media. Particularly in countries where subtitling has been preferred to dubbing (e.g., the Nordic European countries and Romania), the English language is an inevitable part of an evening in front of the television or a cinema visit. Another key domain of multilingual practices in media production is that of advertising and, as Androutsopoulos (2006) points out, this is an area that has received quite a lot of attention from multilingualism researchers.

Originally, it was feared that the Internet would become a monolingual English-language environment, but developments both top-down and bottom-up continue to question this assumption. Technical improvements, many of them driven by countries wishing to push the role of their national language (e.g., Chinese), have meant that non-ASCII-based characters and non-Roman alphabets can now be supported and have in fact become a normal feature of the World Wide Web (Wong, Beaumont, & Konečný, 2006). Multilingualism in the form of parallel monolingualism, with a high degree of English in connection with many languages (e.g., for housekeeping, legal notices), has in fact flourished with the growth of the Internet; as well as this, search engines (e.g., Google), social-networking sites (e.g., Facebook) and online-shopping and corporate Web sites are available in multiple language versions. Many traditionally minoritized languages are enjoying a strong presence, even if in limited registers, on the Web. While this type of parallel monolingualism does serve speakers of different languages and fulfills official language-policy objectives, it can sometimes ignore hybrid and mixed everyday linguistic practices. It also tends to ignore unofficial or everyday multilingualism, and minority languages of allochthonous groups (e.g., Arabic or Turkish speakers in Belgium) in particular can be left out or rendered invisible in this type of approach, even where they constitute a sizable minority within a country. However, bottom-up individual practices on social-networking sites create content on such sites that reflects multilingual, innovative, and hybrid practices, even where the sites themselves are framed in a parallel monolingual way.

The World Wide Web, as one of the most influential and used media environments, serves as an example of the contemporary multiple, even contradictory, language practices and ideologies present in media. Some Web-based multilingual practices such as parallel monolingualism can in fact encourage the idea of monolingualism as the norm, by linking countries and flags to particular languages (Kelly-Holmes, 2005). At the same time, however, some new media, in particular developments in computer-mediated communication, allow for the creation of media texts in a bottom-up way by individuals who are not part of media institutions, and who may be working on their own or simply collaborating with

a small group of individuals (Androutsopoulos, 2006; see also Danet & Herring, 2007, for a range of cases). These types of environment can encourage heteroglossic and mixed practices which reflect language mixing more than traditional media practices (Busch, 2006; Pietikäinen & Piirainen-Marsh, 2009). Linguistic, discourse, and multimodal creativity are involved, supported by, and in some cases practically demanded by the virtual environment, and this provides unregulated spaces where mixed multilingual practices can thrive. For example some of the social spaces on the Internet, especially those which are organized around a particular activity, topic, or game, are heteroglossic: In order for individuals to participate in a meaningful way, they need to have and display a rich repertoire of communicative resources, not just languages but also genres, styles, registers, and discourses.

Virtual media generally tolerate or accommodate a greater degree of non-standard language, some even deriving site-specific norms, which can diverge substantially from top-down norms. For example, languages with no written form or agreed standard are used for communicating on the Web (e.g., in blogs, chat rooms, and discussion forums) by people using their own individual norms and interpreting other people's norms (Wright, 2006). A further dimension that encourages heteroglossic and mixed multilingualism is the fact that users of new media often draw on the features of speech rather than writing, and this makes them very different to old media, the print media having been dominated (and still to a large degree being dominated) by standards of written language, and the broadcast media involving a high degree of scripting, which again links to written rather than spoken language. In addition, unscripted broadcast media have tended to aspire toward spreading a certain norm of language, considered a standard or "higher" form than ordinary everyday speech. However, in the spaces of many new-media environments, the speaker's own everyday language practices can instead be reproduced, and these can easily involve mixed multilingualism. This in turn creates new normative systems for using linguistic and other resources.

Conclusion

As this short contribution highlights, mediation can be seen as both a source of and a block to multilingualism: On the one hand, media can be seen to have contributed (and to still be contributing) to the privileged status of monolingualism in many modern nation-states. On the other hand, media can be seen to be a key way of facilitating and promoting multilingualism, particularly in the context of global, digital media. Contemporary multilingual practices in media reflect the tension between these tendencies. However, it is important to note that these two general points never tell the whole story, and the relationship needs to be looked at on a case-by-case basis. For example, when thinking about national media and the promotion of monolingualism, it is important to remember that the whole idea of strict linguistic borders between countries is more imaginary than real. State borders run through languages rather than contain them. Likewise, it is hard for media not to leak across borders into other states with different official languages and different media-language policies. For those living in border areas, hermetically sealed media borders have never existed, as media products in different languages leak across from other states. For example, Finnish media were part of everyday practices for many neighboring Estonians until the fall of the Soviet Union and the consequent liberalization of media markets. Eurosport, an attempt by the European Broadcasting Union to create a pan-European channel, initially broadcast in only one language (English) but soon had to become multilingual in response to consumers of the channel in different countries—so the pressure to produce nationally specific and monolingual versions (as opposed to a global version)

came from below (from the speaker as consumer), not from the nation-state. These two examples illustrate the complex and constantly changing relationship between media and multilingualism, which makes it a key site for understanding multilingualism in contemporary society.

Multilingualism and Metalinguistic Awareness

CRISTINA SANZ

Introduction

Metalinguistic awareness or explicit, conscious knowledge of form/meaning relationships in a language, usually manifested as the ability to verbalize thoughts about language, is one of the best documented differences between bilinguals and monolinguals. General findings suggest that speakers of multiple languages have greater metalinguistic awareness and develop this awareness at an earlier age than those who speak only one language (Ianco-Worrall, 1972; Ben-Zeev, 1977; Diaz, 1985; Galambos & Hakuta, 1988; Thomas, 1988; Galambos & Goldin-Meadow, 1990; Bialystok, 1991; Ricciardelli, 1992; Yelland, Pollard, & Mercuri, 1993). There are different types of metalinguistic awareness, namely word (Ben-Zeev, 1977; Bialystok, 1988; Ricciardelli, 1992), syntactic (Bialystok, 1986; Galambos & Goldin-Meadow, 1990; Gathercole, 1997), phonological (Yelland et al., 1993; Bialystok, Majumder, & Martin 2003), and semantic awareness (Ianco-Worrall, 1972). Metalinguistic awareness is only one of the cognitive advantages resulting from living with two languages. Although, in comparison, the results for positive effects of multilingualism on the development of metalinguistic awareness are quite robust, a number of variables, including age, level of proficiency (Cummins, 1976, 1981), biliteracy (Sanz, 2007), language typology of the bilingual (Al-Dossari, 2004), and the nature of the task used to measure the effects (Bialystok, 1999, 2001) are believed to interact and explain some of the contradictory findings regarding positive effects of multilingualism on different aspects of cognition. Differences in metalinguistic awareness between monolinguals and bilinguals have been found for adults too (Thomas, 1992). Metalinguistic awareness is posited as a key factor in explaining the bilingual edge; that is, multilinguals' enhanced capacity to learn further languages (Swain, Lapkin, Rowen, & Hart, 1990; Cenoz & Valencia, 1994; Sanz, 2000) and to achieve literacy (Bialystok, 2007a).

Research on multilingualism and metalinguistic awareness is varied in approach. Some of the research comprises case studies (Moreno-Zazo, 1998; Maneva, 2004) and comparisons of mono, bi- and multilinguals in laboratory settings (Nation & McLaughlin, 1986) or classroom/school settings (Sanz, 2007). Naturally, the procedures implemented in this research are as varied as the research itself, varying from participant observation to language proficiency tests and language tasks that elicit superordinate, communicatively adequate definitions, rich/poor object descriptions, word/object associations, grammaticality and semantic congruence judgments, error correction, sound substitution, and word length, to name just a few.

Multilingualism and General Cognitive Advantages

Metalinguistic awareness is only one of the cognitive advantages resulting from living with two languages. The study of the effects of bilingualism on cognition has also implemented non-verbal tasks, such as mathematical and numerical (Bialystok & Codd, 1997),

The Encyclopedia of Applied Linguistics, Edited by Carol A. Chapelle.

creativity (Kessler & Quinn, 1980), and problem-solving tasks (Bialystok & Majumder, 1998; Bialystok, 1999; Bialystok & Martin, 2004), with findings supporting those from verbal tasks (Kessler & Quinn, 1980, 1987) showing that language experience may play an important role in the development of abstract thought (Rosenblum & Pinker, 1983) and semantic creativity. All these studies compared monolinguals and bilinguals completing tasks that varied in their degree of difficulty, with the most demanding tasks requiring that participants ignore irrelevant information that would interfere with the actual task if given attention. These results support previous research (Bialystok, 1988) showing that bilinguals are better than monolinguals at solving problems that are based on conflict and attention.

Although the majority of studies have looked at the cognitive effects that child bilingualism has on cognition, research has also indicated that some of the results found in children can be replicated with adults, and that, in fact, bilingualism attenuates the effect of aging on cognitive control (Bialystok, Craik, Klein, & Viswanathan, 2004; Kefi et al., 2004). Moreover, some studies showed that the positive effects associated with bilingualism may decrease in young adults, who are at the peak of their attentional abilities, when compared to children or older adults (Bialystok, Martin, & Viswanathan, 2005; Bialystok, Craik, & Ruocco, 2006; Bialystok, Craik, & Ryan, 2006).

More accurate descriptions of how bilingualism affects cognitive performance, according to Bialystok (2007b), have led to the interpretation that bilingualism must be considered in terms of both advantages and disadvantages. This has been investigated in studies of cognitive and linguistic processing in adults and in children (see the section below on metalinguistic awareness and reading). For adult bilinguals, recent research has shown that they are at a disadvantage on tasks measuring lexical retrieval and fluency (Michael & Gollan, 2005) but that they are better at controlling attention when performing a challenging task (Bialystok et al., 2004). However, the lack of conclusive results in some of the areas investigated suggests that further research is still needed to understand the complex nature of the relationship between bilingualism and cognition, including metalinguistic awareness. Given that the majority of the research has been carried out with bilingual children as subjects, research must further expand on the recent findings that have examined the consequences of adult bilingualism, especially in young adults, an age group where the bilingual advantage seems to be less obvious.

The language teaching profession considers that the body of empirical studies showing that second language learning fosters cognitive development and contributes to stronger native language skills, especially in writing, is significant enough that they can use it as a convincing argument in favor of the strengthening of foreign languages in school and college curricula (Kecskes & Papp, 2000). Foreign-language learning, even at an intermediate level, improves critical thinking and context-dependent processing of language material, enhances the development of interpersonal relations, and teaches self-reflection on language behavior (Sanders, 2006).

Types of Metalinguistic Awareness

Research investigating cognitive advantages for bilingual children has revealed that bilingualism helps develop higher levels of mental flexibility and metalinguistic awareness at an earlier age. Children exhibit bilingual awareness after their second birthday through self-repair, other-repair, translation, and labeling of languages (Mishina-Mori, 2004). Two year olds can make corrections, criticisms, or initiate language games (Moreno-Zazo, 1998). Bialystok (2001) summarizes several studies that investigated the effects of bilingualism on word awareness, syntactic awareness, and phonological awareness. In word awareness,

a number of studies agree on the advantage of bilinguals over monolinguals in their ability to separate word and meaning (Ben-Zeev, 1977; Bialystok, 1988; Ricciardelli, 1992). However, counterevidence also exists, as shown in a study by Rosenblum and Pinker (1983), a group of monolingual and bilingual preschoolers were equally capable of associating objects with new arbitrary names. Nevertheless, monolinguals and bilinguals varied in the way they referred to the properties of an object. Whereas monolinguals were more likely to talk about the physical attributes, bilinguals emphasized the social context in which objects could be used, thus revealing bilinguals as more capable of extrapolating the meaning of a word and connecting it to the real world.

In the field of syntactic awareness, research has observed an advantage for bilingual children over monolinguals when performing tasks that require noting and correcting errors (Galambos & Goldin-Meadow, 1990) or avoiding misleading information (Bialystok, 1986, 1988). Galambos and Goldin-Meadow argue that bilingual children have a greater awareness of linguistic forms than monolingual children, and that metalinguistic awareness improves with intellectual development. However, studies dealing with morphosyntactic structures have also shown that there are areas in which bilinguals do not outperform monolinguals, such as the acquisition of the mass/count distinction in English (Gathercole, 1997). This study examined whether bilingual children differ from monolingual in the way they draw inferences about the referents of new nouns based on mass/count structures such as *an* X and *some* X. The results showed that young monolinguals (seven years old) outperformed bilinguals of the same age. However, at nine years old, bilinguals seemed to have achieved the same levels of performance as their monolingual counterparts. Gathercole (1997) provided a number of possible explanations for these results; the one that seemed more plausible is that bilinguals may just need more time to acquire this specific feature. The differences in results between this and other studies in the area may also lie in the nature of the task. In this case, either an elicitation task (Gathercole, 1997) or a grammaticality judgment task that requires the inhibition of misleading information (Bialystok, 1986, 1988; Galambos & Goldin-Meadow, 1990) were used. In addition, this study suggests that the difficulty of the task proposed may play an important role on the effects of bilingualism on cognition depending upon the age and developmental stage of the participants.

In phonological awareness, positive findings for bilingual children are revealed in aspects such as the ability to judge whether objects in pictures had long or short names (Yelland et al., 1993). However, Bialystok et al. (2003) did not find any difference in performance between bilingual and monolingual children who were requested to substitute a sound in the target word with another sound from another word.

According to Ianco-Worrall, bilingual children appear to develop semantic understanding before monolingual children, although this difference diminishes over time. Ben-Zeev concludes that bilingual children are better prepared to reorganize their perceptions than their monolingual counterparts, and that bilingual children are prepared to treat words as units separate from their semantic content within a greater syntactic system.

Conditions Affecting the Development or Use of Metalinguistic Awareness

Proficiency Thresholds in Two Languages

To resolve some of the contradictory findings from studies investigating the relationship between child bilingualism and cognition and specifically to explain some of the negative findings that had been obtained in research with minority and migrant bilingual children in subtractive contexts (i.e., where two languages are competing), Cummins developed a

new framework (1976), the Threshold Hypothesis. Cummins related cognitive development in children, internal in nature, to the attainment of proficiency thresholds in their L1 and L2, and this to a combination of external (i.e., social, attitudinal, educational) factors. Under the model, bilinguals are expected to develop cognitive advantages, including metalinguistic awareness, when compared to monolinguals, only after a certain threshold is reached in their L2 (second threshold in Cummins's terms).

Bialystok pointed out to the importance of the factor "level of bilingualism" proposed by Cummins in determining different levels of metalinguistic awareness, and proposed the inclusion of a more fine-grained distinction that incorporates different degrees of proficiency (not just balanced or unbalanced). This proposal is supported by the findings on the effects of a range of levels of proficiency, which included not only benefits for partial bilingualism (Bialystok, 1988; Yelland et al., 1993), but also advantages only for fully balanced bilinguals (Ricciardelli, 1992), a greater advantage for fully balanced bilinguals (Bialystok, 1988; Cromdal, 1999), or disadvantages for partial bilingualism (Gathercole, 1997). Consequently, an explanation of the bilingual advantage requires the inclusion of more complex factors that should interact with the "level" explanation.

Research has in fact provided evidence that higher levels of bilingualism are associated with cognitive advantages when compared to lower levels of bilingualism not only in children (Bialystok, 1988; Ricciardelli, 1992; Bialystok & Majumder, 1998) but also in adults (Thomas, 1988; Kefi et al., 2004). For children, studies such as Yelland et al. (1993) found that children who had received partial instruction in Italian (i.e., they were not totally biliterate) as second language were better than monolinguals at judging whether a number of pictures contained long or short names. Other studies also suggest that being partially proficient in a second language confer participants with a cognitive advantage when compared to monolinguals in tasks that involved metalinguistic awareness. Bialystok (1988) compared three groups of children: 20 English monolinguals, 20 partially French-English bilinguals, and 17 fluent French-English bilinguals. Participants were exposed to two tasks: *arbitrariness of language* and *concept of word*. Whereas the first one assessed the child's understanding of the arbitrary connection between linguistic form and reference in the world, the *concept of word* task assessed the child's knowledge of the abstract concept of a word. The results revealed that the two bilingual groups outperformed the monolingual group on the *arbitrariness of language* task, and that the fully bilingual group performed significantly better than the other two groups on the *concept of word* task. Similarly, Demont (2001) shows an advantage for children who attended German/French bilingual classes since kindergarten at grammatical judgment and correction tasks and word recognition, while Dillon's comparison (2009) of children in both early total immersion schools (Gaelscoileanna), where Irish is the language of instruction, and English-medium schools, where Irish is taught as L2, concluded that more balanced bilinguals are more likely to independently display higher levels of metalinguistic awareness and evidence of cross-linguistic transfer. Parallel conclusions were drawn by Kenner, Gregory, Ruby, and Al-Azami (2008) for second and third generation Bengali heritage language learners in the UK. In conclusion then, evidence suggests that the higher the level of bilingualism, the more cognitive advantages, but when a partial level of bilingualism is reached benefits also appear when compared to monolinguals.

Studies with adult participants, like that of Thomas (1988), show comparable results in that with more linguistic experience comes greater metalinguistic awareness. Thomas maintains that bilinguals who have learned a second language in the classroom show a greater ability to learn a third language than bilinguals who have not received formal instruction in their second language, and therefore have not been exposed to grammar

explanations. According to Thomas, instruction aids in the development of sensitivity to grammar. More recent research by Ransdell, Barbier, & Niit (2006) compares working memory capacity and metalinguistic awareness as it applies to reading in monolingual, bilingual, and multilingual university students within three cultural contexts, America, Estonia, and France. Their results show that bilingual and multilingual students have better metalinguistic awareness of their language skills in reading and greater working memory capacity than do students who are monolingual, but who have comparable native language skills. Gibson and Hufeisen (2006) also concluded that multilingual learners of English are highly metalinguistically aware and adept at sifting formal grammatical information from semantic information both in listening and written task. In conclusion, more research is needed to determine where, on a scale from low to balanced adult bilingualism, Cummins's second threshold can be placed. In addition, another relevant issue should be addressed: whether there is more than one adult threshold and whether these thresholds are held constant for different cognitive abilities and external conditions.

Within the discussion on levels of proficiency, some scholars attribute the cognitive benefits of bilingualism to literacy in two languages (Cummins, 1981; Swain et al., 1990; Cook, 1997; Bialystok, 2001). For example, Swain and colleagues investigated the effect of L1 literacy on L3 learning among 319 eighth graders in Toronto. Results of this study suggest that the crucial factor in successful L3 acquisition is the development of heritage language literacy skills, rather than exclusively oral skills as well as language typology of the bilinguals. Likewise, Sanz (2007) establishes a relationship between literacy development in two languages and enhanced ability to learn an L3. As expected, no effects were found for balance in oral skills, but regressions show level of biliteracy is a predictor, and ANOVAs show that there is a specific level of development of literacy in both languages that needs to be reached before we can observe enhanced ability to learn the L3, possible in socio-educational situations that promote additive bilingualism. In considering these arguments, the reader should bear in mind the typological relationship between the languages involved. Both Catalan and Spanish are Romance languages, therefore, further research is necessary that incorporates the same variables in a comparable socio-educational context that involves typologically different languages, as it is possible that biliteracy in two distant languages further enhances metalinguistic awareness.

Nature of Task

A second explanation to account for contradicting behavior elicited by metalinguistic tasks was proposed by Bialystok (1999, 2001). Her framework describes to what degree task characteristics determine a bilingual's performance depending on the involvement of two processing components: analysis and control. Whereas analysis is defined as the ability to represent explicit and abstract rules, control is described as the ability to attend to specific aspects of the input, especially in situations that include ambiguous information. In order to test how bilingualism interacts with these external conditions, the task is manipulated such that demands of analysis and control are increased. Reexamining the results in this way reveals that bilingual advantages occur reliably on tasks that make high demands on control but are not evident in tasks that make high demands on analysis.

Bilinguals' greater attention to language form to determine constantly which language to use and how to switch between languages develops the component of control which serves as a guide during this linguistic process. Also, reading decontextualized language in comparison to oral exercises demand a greater understanding of the grammatical structure, making easier the development of the analysis component. Biliteracy is key in developing the analysis component.

What is the Use for Metalinguistic Awareness? Learning to Read, Learning Other Languages

Metalinguistic Awareness Enhances Acquisition of Non-Native Languages

A number of factors involved in language acquisition may be enhanced as a result of the language-learning experience of bilinguals, including cognitive flexibility, automatization of skills, and metalinguistic awareness (Cummins, 1976; Cromdal, 1999; Bialystok, 2001; Gibson & Hufesien, 2006).

Such factors have been posited to explain the advantage shown by bilinguals over monolinguals in the acquisition of a third language (L3) both in classroom (Swain et al., 1990; Cenoz & Valencia, 1994; Sanz, 2000) and in laboratory studies (Nation & McLaughlin, 1986; McLaughlin & Nayak, 1989; McLaughlin, 1990; Nayak, Hansen, Krueger, & McLaughlin, 1990). Classroom studies conclude that instruction in the minority language is associated with improved competence in an L3 at no cost either to competence in the majority language or to academic development. In Sanz (2000) Spanish-Catalan biliterates were shown to have an advantage over Spanish monolinguals as learners of English as an L3. She concludes that, in general, bilinguals are more efficient language learners because they are faster and consequently achieve a higher level of attainment in the L3. But what gives multilinguals the edge? From a cognitive psychology perspective, bilinguals are experienced language learners and users and experience allows them to approach the task of learning a new language in a different, more efficient way. From a second language research perspective, metalinguistic awareness works as advanced organizer for incoming linguistic stimuli.

In second language acquisition research, whether conscious knowledge of a language (metalinguistic knowledge) can be transformed into implicit, unconscious knowledge (considered true competence) is a matter of discussion, but most agree that it can help in the acquisition process by acting as an advanced organizer, focusing learners' attention on the relevant features of the language. That is, bilinguals' heightened metalinguistic awareness, which results from exposure to more than one language and especially to literacy in two languages, gives them the capacity to focus on form and to pay attention to the relevant features in the language input, thereby increasing the amount of intake (processed input) that feeds into their interlanguage system (internal grammar).

In cognitive psychology, a pattern of evidence has emerged in studies that compare experienced and inexperienced learners. Experienced learners tend to restructure the elements of a task into schemata that are seemingly unavailable to inexperienced learners. During restructuring, isolated subelements of a task are consolidated into related units and this consolidation allows for further abstract processing at lower cost than processing of disconnected and isolated subelements. This general cognitive explanation is exemplified by Klein (1995), whose multilinguals showed heightened ability to identify and retain key verbs necessary to trigger the parameter resetting for preposition stranding, the key form to be acquired. Similarly, Sanz (2000) concluded that language experience may influence input processing in bilinguals, who may spontaneously display what classroom pedagogical techniques try to induce: focused attention to key features in the input (Doughty & Williams, 1998).

In a series of studies on bilingualism and cognition (McLeod & McLaughlin, 1986; Nation & McLaughlin, 1986; McLaughlin & Nayak, 1989; Nayak et al., 1990), McLaughlin's research team attempted to demonstrate that both bilingual and multilingual individuals have an advantage over monolinguals in automation and restructuring processes. Nation and McLaughlin (1986) compared the performance of "novice" (monolingual English) and "expert" (bilingual and multilingual) learners as they were exposed to a miniature linguistic

system under implicit (read and memorize) and explicit (read and search for grammar rules) learning conditions. They found that the experts outperformed novices in the implicit but not the explicit condition. The results of this study give evidence to the relationship between previous linguistic experience, memory, and language learning: multilingual subjects are better equipped to process a constant stream of information, keeping in working memory only that which is relevant to further processing. In the explicit condition, where these processes are unnecessary, the multilingual group did not show any advantage.

In the light of these results, it will be important to determine if bilinguals at different stages of L2 development make different use of explicit information (grammar explanation, feedback) during the acquisition of a third language. Within the Latin Project (a long-term study led by Sanz, Stafford, and Bowden), Lado's dissertation compares performance by 151 basic, intermediate, advanced, and native-like speakers of L2 Spanish during the initial stages of development of an L3 under two computerized treatments which differ in the type of feedback (+/- explicit). Accuracy and latency in four different tests show that level of bilingualism is closely related to L3 proficiency level (e.g., Cenoz, 2003) and that even partial bilingualism enhances subsequent language learning (e.g., Thomas, 1988), although these benefits appeared under less challenging conditions, that is, when the rules were provided or when the tasks were less demanding. Importantly, as hypothesized, the study identifies the presence of one or two thresholds for the positive effects on cognition of adult bilingualism, with positions changing depending on external conditions. Under more demanding conditions (i.e., -EF [less explicit feedback] and more cognitively demanding tasks), only one threshold emerges and is delimited by near-native proficiency. The appearance of these thresholds is explained with aptitude—as measured by the modern language aptitude test (MLAT)—and working memory (WM) capacity (as measured by a sentence span test), which suggests that for adults learning an L2 in formal contexts, achieving a high level of proficiency results in a cognitive edge.

To sum up, experience with more than one language—multilingualism—promotes the automation of the basic necessary abilities in the processing of information and language. As they become automatic, these basic necessary abilities depend less on working memory and allow room for other processes. Also, the development of input restructuring strategies is a result of metalinguistic analysis. Language learners restructure input in categories that allow for quicker access and more transparent relationships with other units of information, making the processing of new input definitively easier. In this way, multilingualism, metalinguistic awareness, and attentional control are interconnected and explain multilinguals' advantage in the acquisition of new languages.

Multilinguals and Metalinguistic Awareness as a Facilitator of Literacy

The research on literacy agrees there are three prerequisite skills for the acquisition of literacy: establishment of metalinguistic awareness, competence with the oral language, and understanding of symbolic concepts of print (Bialystok, 2007a). Research on bilingualism and literacy explores the extent to which these skills differ for monolingual and bilingual children. Its findings suggest that bilingualism is clearly a factor in children's development of literacy, but the effect of that factor is neither simple nor unitary. Sometimes bilinguals are at an advantage (concepts of print), sometimes at a disadvantage (oral language competence). Likewise, Francis (1999) concludes that metalinguistic awareness is related to difficult aspects of literacy development in different ways, the key variables being the degree of decontextualization and expressive versus receptive language tasks.

Multilingualism and Minority Languages

COLIN H. WILLIAMS

The interaction between hegemonic state languages and autochthonous or allochthonous minority languages is a fascinating, sometimes tragic, relationship, interpreted here from a sociopolitical and policy-related perspective. As one of the chief components of group identity and the means by which the ideas and techniques of social development are diffused, language is one of the most sensitive issues of the contemporary world. Language issues are often an overarching mobilizing factor within which other goals are pursued. It follows that a sovereign state's approach to language management can be a key determinant of the degree to which political unity and the rate of economic "development" are achieved. If a language policy is harmonious and effective, it releases collective energies into other more profitable avenues. If it is authoritarian, divisive, and dysfunctional, it can lead to alienation, pressures for regional separatism, and ultimately to civil war or disintegration.

Political integration is central to state stability as the incorporation of ethnically differentiated territories has been a necessary precursor to the creation of the territorial-bureaucratic state. Incorporation strengthens central rather than local interests, and serves to threaten the material and spiritual sustenance which incorporated groups derive from their immediate locale. Patterns of state integration and development are often overcentralized without a corresponding attention to the needs of the "periphery," except the need to integrate it politically and strategically. This has led to charges of core discrimination, peripheral marginalization, and the denial of group rights and cultural reproduction. For some these features are a necessary product of global development; others query whether or not the denial of distinctiveness is too high a price to pay for their economic and bureaucratic incorporation into the mainstream.

For many peoples, state integration has resulted in the conquest of ethnic territory, the denial of popular rights, and the external development of their homeland. Many ethno-linguistic minority groups perceive their territory as having been under threat in modern history, whether through forced out-migration as a result of land enclosure, such as Scotland in the 18th-century clearances or apartheid South Africa after 1948; of famine, such as Ireland in the 1840s, Sudan in 1980–94, and Ethiopia in 1984–94; of resource exploitation, as happened to the Māori or Canada's First Nations and Inuit; or rapid externally derived industrialization, as in Euskadi in the late 19th century. Another factor is internal migration, such as the huge migration of English workers into 19th-century Wales or the successive waves of migration from Andalusia to Catalonia which reached its height in the 1960s (Solsona, Ajenjo, Treviño, & Jiménez, 1995; Hernández, 2007; Querol Puig & Strubell i Trueta, 2009).

Consequently, one of the most malleable and durable resources which a minority can employ in their struggle for recognition and participation is language. Because institutional means of dissent were often denied them, subject peoples invariably focused on cultural diacritical markers as a means of asserting their own separateness and demonstrating their resistance to external state and commercial incursions into their territory. Questions of language, culture, and identity can constitute the very essence of a subordinated group's

relationship with the state in whose name the dominant group exercises power and control. As group identity and power differentials are rooted in their environment and expressed through material acts of construction or change, it is not surprising that any threat to the immediate territory of a subordinated group is interpreted as a challenge to their culture and group survival. Place, boundaries, and territory are critical in the process of control and development and their appropriation by external agencies has a long history related to the extension of state hegemony and strategic, capital projects of “state building” and “nation formation,” which are essentially contestations over space.

Historically, we can identify four types of language policy which structure the relationship between multilingualism and minority languages, and each has a different trajectory in the processes of state formation. The first and most common—as found in France—reinforced political and cultural autonomy by giving primacy to one indigenous language as the language of government, administration, law, education, and commerce. A number of goals were achieved simultaneously, such as the search for national integrity, the legitimization of the new regime and its state apparatus, the reestablishment of indigenous social organization, the reduction of dependence upon external organizations and influences, and the incorporation of all the citizenry into a wide range of para-public social domains. Foreign languages were reserved for the specialized functions of higher education, international diplomacy, and commerce. In the past 40 years a historically similar policy, as applied in the United Kingdom and Spain, has been subjected to quite radical reforms including regional autonomy and devolution, resulting in the increased salience of Catalan, Basque, Galician, Welsh, and Gaelic as official languages of education, public administration, IT, and broadcasting in their respective territories.

A second type of language management characterizes those situations in which the “national” goal has been to maintain cultural pluralism, so that the state might survive through containing its inherent tensions. Under this system, language was used to define regional associations rather than state or national citizenship. Thus of Switzerland’s 26 cantons three are bilingual, one (Graubünden) is trilingual, and the remainder incorporate cantonal unilingualism within a multilingual federal system. A less consensual solution has been the rigidly enforced division of Belgium between its Walloon- and Flemish-speaking populations.

The third alternative applies when a recognized minority is granted some degree of geographical distinction, based upon the territoriality principle of language rights, but without gaining full regional autonomy. In Finland, shared historical context, high levels of language contact along the west coast, marked religious uniformity, a strong tradition of centralized government, and the unifying effects of long-term external threats led to a recognition that the minority Swedish-speaking population should be accorded official status. Following the 1922 Language Law, all communes were classified as unilingual Finnish, unilingual Swedish, or bilingual if they contained a linguistic minority of either group of 10% or more; these classifications were revised after each decennial census to take account of changing linguistic geography (McRae, 1997).

A fourth option—the modernization or revitalization of an indigenous language—characterizes societies disengaging from colonial relationships and the cultural hegemony of a dominant state. Language mobilization was a key goal of the 19th-century nationalist intelligentsia in Hungary, Ireland, Finland, and Norway prior to independence, and remains a consideration in those states which have not succeeded in fully instituting the indigenous language as a popular medium of governance and civil affairs—as in Ireland, which in December 2010 announced its 20-year strategy for the Irish language (Government of Ireland, 2010). Another aspect of modernization can also involve the introduction of a new language or linguistic variety in order to replace a defunct variety. There has been a long-standing discussion in Friuli (Friuli in northeastern Italy) as to which variety of

German should be taught in schools in the Germanophone linguistic islands (Tischelwang, Lusern, Pladen). Similarly in Schleswig-Holstein the standard Danish variety "Rigsdansk," introduced by the Danish authorities, has replaced the local dialect of Jutish. Thus an indigenous variety is being replaced by an allochthonous one, but it remains a salient identity marker for the local populace.

How do these macrolevel policies and strategies transform into microlevel action which informs public services, education, and legal affairs? Language policy and planning in any multilingual society are a public good and are as capable of being manipulated as any other aspect of state policy. Nevertheless, it is an essential feature of the economic and political restructuring of many states. The key issues are:

- Who decides—and on what basis—such bilingualism or multilingualism is to be constructed?
- Which languages are chosen?
- Who benefits by acts of state-sponsored social and identity formation?
- How is language-related conflict managed and reduced?
- How is language planning to be related to all other forms of social intervention?
- How do citizens respond to reformed language regimes?
- How do such reforms relate to international trends in education, human rights, freedom of mobility of labor and skills acquisition?

The recognition of the need to honor rights and plan language services normally involves the use of a previously disallowed language within public administration and the legal system, a religious-based education provision, or differentiated access to the media. Such reforms may be predicated on the basis of a personality (i.e., related to the status of the individual) or a territoriality principle (related to the legal status of the district or region) or some expedient admixture of both, but they are not in themselves sufficient to avoid conflicts. Some conflicts can be partially neutralized if the following conditions are observed:

- The territoriality principle should be limited to a few key areas like administration and education.
- The institutional multilingualism that emerges should lead to the creation of independent unilingual networks, which grant equal opportunity of communication to minority and majority speakers. These networks should also exclude linguistic discrimination connected with speakers of the prestige language.
- Measures of linguistic planning should not be based exclusively on linguistic censuses carried out by the respective governments. Rather, they must genuinely take account of the situational and contextual characteristics of the linguistic groups.
- Minority linguistic groups in a multilingual country should not be judged primarily on quantitative grounds. On the contrary, they should be awarded more rights and possibilities of development than would be due to them based on their numbers and their proportion to the majority. (Nelde, Labrie, & Williams, 1992)

Nelde and colleagues argue that according such equality to minorities by assuring them of more rights could result in fewer people adopting an intransigent ideological position. This may also lessen the incidence of civil war, ethnic conflict, and separatism; however, it does not offer an absolute guarantee, for the target community is often deeply divided and many conflagrations are intensified as a result of external pressures and geopolitical hostilities.

It is debatable whether territorial principles of language protection offer adequate protection to bolster language loss and whether strong language legislation, as in Catalonia

or Quebec, has enabled successive governments sufficient control to regulate language choice and behavior (Generalitat de Catalunya, 2000). The federal government's containment approach is related to the grand narrative which official agencies construct from their distinctive approach to the collection and presentation of official language data as reflected in the Annual Reports of the Commissioner of Official Languages (Commissioner of Official Languages, 2007). Critics of the Canadian approach argue that "Statistics Canada" has chosen to define and interpret official language data in a certain manner which allows successive federal governments to place a more positive gloss on official language policy than is warranted by reality. Castonguay (1997, 1999) argues that trends such as the demographic advantage of English, the collapse of Canada's French-speaking population, the impact of allophone language shift, and the increasing anglicization of Francophones outside of Quebec all demonstrate that the "personality principle" approach to official bilingualism is inherently assimilationist, thus subversive. Cardinal (1999, 2007) offers a cautionary rider to such trends, arguing that the federal language regime has placed Francophone minorities outside Quebec in an unhealthy state of dependency on government and the courts. The acute political point is that they thereby become part of the Trojan Horse federal strategy vis-à-vis Quebec. Thus many critics, such as Chevrier (2003), endorse Dion's (1992) position that the personality solution should be adopted throughout Canada, except in Quebec, where territorialism should be acknowledged as a political fact.

A major difficulty in the general interpretation of the relationship between multilingual politics and minority languages relates to how official data are collected and used as a basis for policy development and periodic reporting. In general there is a lack of adequate time-series data by which to analyze demo-linguistic trends. Various attempts to describe the range of language diversity in the EU (European Union) include the Euromosaic (www.uoc.edu/euromosaic/web/homean/index1.html) and ADUM projects. The EBLUL/ECMI report (2002) combines the Euromosaic and graded intergenerational disruption scale (GIDS) scores in order to create a continuum which ranges from the strongest, "unique" language communities of Catalan in Catalonia, Luxembourgish, Welsh, Basque in the BAC (Autonomous Community of the Basque Country), through a mid-point (GIDS score 4) representing Friulian, Sorbian, Ladin, Asturian, Basque, and Catalan in France, to the weakest represented by East Frisian, Aroumanian, and Cornish. GIDS scores for Regional Minority Language (RML) communities within "kin states" demonstrated that Swedish in Finland and German in Italy were the strongest, with Slovenian in Austria at a mid-point (GIDS score 4), while Dutch in France, Portuguese in Spain, Albanian in Greece, and Greek in Italy were in the weakest position. Regular reports commissioned by the European Commission, together with Committee of Experts Reports regarding the European Charter for Regional or Minority Languages and those pertaining to the European Convention on Human Rights are replete with good insights and sound recommendations, but are too often rendered ineffective because they have little purchase and binding force on the actions of member states.

A second issue relates to the inconsistency by which minority languages are identified and categorized. Extra and Gorter (2001, pp. 7–16) have raised the issue of the criteria used for identification of population groups in multilingual Europe. They argue that while data on Regional Minorities (RM) is recorded on the basis of (home) language, ethnicity, or both, that on Immigrant Minorities (IM) is recorded on the basis of nationality, country of birth, or both. Due to the decreasing significance of nationality and country of birth criteria in the EU it is probable that the combined criterion of self-categorization and home language will characterize future language planning policy. The case studies represented in Barni and Extra (2008) offer a rich illustration of how these various trends are impacting within different European contexts. However, one should be alert to the political implications of choosing certain criteria by which residents in specific programs

are included or excluded and to the attempts by government agencies to put a positive gloss on official language trends. A more worrying issue is the refusal of several states to gather language-related data at all, either because it is politically too sensitive or because it is too expensive.

The emancipation of long-discriminated-against minorities (either through the renaissance of minority languages or through constitutional reform) has also to be set within the context of an enabling infrastructure which allows them to use their new-found rights. Modernized indigenous languages, such as Irish or Catalan, are capable of expansion but are unlikely to displace hegemonic languages, especially within the civil service, or technological and commercial sectors. Other languages such as Welsh, Frisian, or Basque have penetrated new domains, such as local administration, education, and the media, but some of this activity is tokenistic or reaches only the superficial structures of society. In contrast, threatened minority languages such as Romany or Skolt Lapp will be further marginalized. The fact that speakers of lesser-used languages have become highly politicized in the last 20 years should not divert attention away from their fears of cultural attrition. Thus deciding between the promotion of one or many languages in public services or in the educational domain is becoming less of a "free choice." The increasing burdens of economic, social, and cultural development crowd in on the limited resources available for language planning and its implementation. This was demonstrated by the 2004 EU enlargement, when an additional 60 languages fell within the remit of European governments and nongovernmental organizations. These comprise border minority languages, autochthonous languages (Kashubian in Poland, Carpatho-Rusyns in Slovakia), partially migrant languages (Russian in the Baltic States), official languages (Maltese in Malta), and linguistic islands (the Tartars).

Some 50 million EU citizens, 10% of the population, speak a regional or minority language. Some of them are served by language boards or departments established by government to promote linguistic policies. Several ethnolinguistic minorities are engaged in European-wide projects in broadcasting, information networking, education, and public administration, establishing their own networks and entering into new alliances to influence decision-making bodies. They believe that by appealing to the superstructural organizations of the EU for legitimacy and equality of group rights, they will force individual states and the Community to recognize their claims for political/social autonomy within clearly identifiable territorial/social domains and influence patterns of governance as discussed, for example in the European Commission's White Paper of 2001 (European Commission, 2001). The best illustration is the Network to Promote Linguistic Diversity (NPLD), established in 2007 (www.npld.eu), part-funded by the Commission's Lifelong Learning Programme, which encompasses regional, minority, indigenous, cross-border, and smaller national languages. The Network's aim is to facilitate the sharing of best practice and the development of innovative ideas, especially within the priority areas of intergenerational language transmission and preschool learning, motivation and increasing usage of target languages, and the wider deployment of RMLs in health-care services.

At the heart of the debate on European identity lies a consideration of the role of hegemonic languages as both symbol and instrument of integration. A burning question for many is whether English should be encouraged as the official language enabling most Europeans to communicate with each other. Or is it desirable (or even possible) to attempt to slow down its inevitable global spread?

The growth and displacement of languages often defies conventional explanation, let alone accurate planning, because while access to information and power demands fluency, it also requires investment in institutional structures, the deployment of technical facilities, and the improvement of skills and capacity so as to access the "opportunities" afforded by the new digital age.

There is also the pedagogical issue as to how many languages a school student can reasonably be expected to learn, for in many instances parents are reluctant to expose their children to more than two “foreign” languages, and as English is so pervasive this may have severe consequences for the transmission of selected minority languages within the school system.

Logically, if globalization and interdependence can enhance the productive capacity of majority, “nation-state” interests, they can also be harnessed to develop the interests of lesser-used language groups. Looked at historically, the recognition of linguistic minority demands is a very recent phenomenon. In accordance with the resolutions of the European Parliament (Arfé, 1981; Kuijpers, 1987; Killilea, 1994), the European Community since the early 1980s has occasionally supported action to protect and promote its constituent regional and minority languages and cultures (European Commission, 2010). There has also been the development of legislation and declarations upholding the rights of minorities to use their languages in several domains, most notably those overseen by the Council of Europe whose various resolutions have resulted in the emergence of basic standards for language rights (de Varennes, 2009). However, these applications are inconsistent and do not have the same force in law as do appeals to the European Court of Human Rights; thus linguistic minorities still face many structural barriers to their full participation within the EU system.

One place where there has been an attempt to restore a sense of balance and to manage complex multilingual trends is Catalonia. In the 1960s and 1970s Catalonia experienced a net inflow of relatively unskilled migrants from poorer, rural regions such as Andalucía and Extra Madura. A second migratory flow, whose origins are in North Africa, Latin America, and parts of Asia, is more recent and ongoing. The language of social integration of these migrants faced with housing, employment, and health access issues is Spanish, even if the desired long-term policy goal is to transform these immigrants into functional Catalan speakers. The fear, of course, is that the cumulative numerical influence of such migrants will serve to weaken Catalan as a default language of social interaction, especially within urban areas. The other related fear is that calls for the primacy of Catalan, in contexts where even a modicum of Spanish would be a major achievement for many migrants, can be interpreted as a cover for social exclusion and incipient racism. This is why the related question of immigration and multilingualism is so sensitive. Issues of class, race, deep culture, and religion are heavily intertwined with the broader patterns of social cohesion as respective speakers of Catalan and Spanish both seek to “normalize” their preferred language as the language of social interaction.

Given such tendencies, repeated within most large metropolitan nodes in Europe, there is growing pressure for a pan-European educational policy that stresses statutory and professional instruction for multilingual communication. Specialists stress education’s potential in promoting cultural awareness (Baker, 1996). The outstanding questions produce periodic partial solutions in relation to what role the mother tongue should have in formal education for minority group members, whether students should be required to learn the national language of one of their neighboring states, whether there should be consistency in providing a range of minority language opportunities from the kindergarten up to university level, and on what grounds certain non-European languages should be privileged within the education system at the expense of other languages, whether European or not. All of these questions and their detailed implementation remain the subject of public contestation and political debate.

Whether or not one accepts the legitimacy of these questions, the underlying tenets of liberal multiculturalism depend to a large extent on the relative vibrancy of the target groups within a European policy of multilingual education. What started as an attempt to preserve a common Western heritage now has to adjust to the reality of managing divergence in a multiracial society. France, Sweden, and the Netherlands have enacted

protective measures which seek to combat the pervasiveness of English. How vibrant are Europe's constituent cultures? How dependent are they on official patronage? Are they self-sustaining or are many perpetuating a generation-specific conception of a subculture, subsidized by public coffers? Clearly such questions draw attention to the dualistic relationship of culture and the modern state. Most minority languages are increasingly dependent upon the state for legitimizing their access to the media, for granting them permission to establish bilingual or religious-based schools, for upholding in law several of their key fundamental values and principles. However, when language and the culture it represents become institutionalized in new domains via new agencies, such reforms change the relationship between the individual and the state. Power for enfranchisement is the key to how successful such a relationship will be in serving the needs and expectations of a multicultural society.

Key questions inform the formulation of multilingual strategies; thus we may ask:

1. What are the strategic needs for language development in Europe?
2. Whose interests are served by pluralism in language development?
3. To what extent is democracy undermined by the unsatisfied aspirations of threatened language groups?
4. Are OLS/IML (Other Language Speakers/Immigrant Minority Languages) necessarily to be conceived as competitors to autochthonous RML (Regional Minority Language) groups in the field of language policy and basic rights?
5. Are the nonterritorial claims of OLS/IML groups sufficiently well developed to have a sociospatial impact on the provision of local services within public administration?
6. What is the role of language in education for the adequate rendering of social and health services and how does one avoid creating a demand for particular languages at the expense of others?
7. What are the different critical masses required for particular services?
8. How do the central agencies of social reproduction, such as the law, education, and health, relate to the increased demands of pluralism and strive to satisfy such demands within a multicultural system? (Williams, 2008)

EU harmonization policies which strengthen majority language regimes pose a threat to the vitality of some regional and immigrant minorities. Sympathetic states, such as Ireland and Finland, together with regional parliaments in Catalonia and Wales, have moved from a preoccupation with the promotion of minority languages to a more legislative and regulatory basis for language management, initially within the public sector, but increasingly within a wider range of socioeconomic activities. Thus the operation and sociolinguistic impact of agencies such as An Coimisinéir Teanga (2009), the Catalan Language Guarantees Office, and the Welsh Language Commissioner will prove an important regulatory filter by which one may measure the degree to which strident minority languages navigate a path through an increasingly multilingual world order. As for the less strident languages, their fate depends less on the political control and resource allocation of the regional state, and more on their ability as supplicants to appeal to a modicum of decency and equality of treatment within international law and conventional representative democracy. The key actors in any multilingual state are the members of the majority society and it is to their interests as fellow citizens that minority language tactics are increasingly directed, so that issues of language become less and less concerned with division and conflict and more and more with treating the multilingual heritage as a public good. Such sentiments are hard to gainsay in relatively affluent times, but will be sorely tested in times of periodic economic recession and social tension.

Multilingualism and Philosophy

LARISSA ARONIN AND DAVID SINGLETON

It might have been imagined that a philosophy of multilingualism could draw copiously on the long-established concepts and procedures of the philosophy of language. However, much of the work undertaken by philosophers of language is of minimal relevance to current multilingualism—a phenomenon sometimes labeled a *new world order* (Fishman, 1998). Among the new realities one can cite the changed *role* of multilingualism in our present world, where so much now depends on multilingual arrangements and individuals. *Complexity* is also a salient feature of contemporary multilingualism—a concomitant of the dramatic rise in the number and significance of multilingual migrants and multilingual communities, which has enormously extended the *scope* of current multilingualism. Finally, at both individual and community levels, *constellations of languages* often fulfill the communicative, cognitive, and identificational requirements once met by single languages.

Some Previous Avenues of Philosophical Interest in Language

Philosophical interest in language has been largely oriented toward questions regarding the connections between language, mind, and the world, as well as toward language-related methodological issues in philosophy. It has often impregnated the philosophy of science, because of the crucial importance of precision of language and meaning in scientific discussion. Frege (e.g., 1972 [trans. Bynum]), the progenitor of analytic philosophy, and widely regarded as a founding father of the philosophy of language, interested himself in language out of a desire “to free thinking from the fetters of language by pointing up the logical imperfections of language” (cited Beaney, 2006, p. 61), a direction that dominated 20th-century Anglo-American philosophy, in which language was seen as the primary locus for philosophy. This approach was encapsulated in Wittgenstein’s claim that all philosophy is “critique of language,” “a battle against the bewitchment of our intelligence by means of language” (Wittgenstein, 1953, §109) by uncovering the rules of logic *underlying* our language-games.

The preoccupation with language launched a variety of philosophical schools and styles—logical atomism, logical positivism, ordinary language philosophy, formal analysis, and linguistic phenomenology. In all such approaches language was seen as important because of its interposition between reality and our apperception thereof—distorting, concealing, symbolizing, communicating, or constructing, depending on the particular stance taken. The relationship between linguistic expressions, sense, and truth was discussed in Russell’s (1905) theory of descriptions, as well as by logical empiricists, most of whom were “philosophically engaged scientists” (Baldwin, 2006, p. 72) whose primary concern was to construct a language which would serve the needs of science. Quine (1970) for his part developed the notion of “indeterminacy of translation.” Some philosophers of language, on the other hand, turned their attention to the positive role of “ordinary language” in our understanding of concepts (e.g., Austin, 1975).

A broader approach is a perspective peculiar to Russia (Bezlepkin, 2002). It significantly broadened the context of language issues and moved beyond the confines of the logico-gnoseological framework. Russian thinkers tended to construct their view of language on

a national and spiritual foundation, so that language was often considered primarily in the light of its general value as the carrier and expression of spirituality and nationality.

More recently Chomskyans have revitalized the idea that an innate language capacity is what distinguishes human from animal cognition—a capacity which “determines what counts as linguistic experience and what knowledge of language arises on the basis of this experience” (Chomsky, 2006, p. 24). This nativist claim arose in opposition to the behaviorist view that the child starts life as a *tabula rasa* and “acquires verbal behavior when . . . vocalizations, selectively reinforced, gradually assume forms which produce appropriate consequences” (Skinner, 1957, p. 31). The debate between Skinner and Chomsky is a version of the millennia-old nature–nurture debate. Nativists differ among themselves regarding the evolutionary origins of the language faculty. Whereas Chomsky sees it as a by-product of the evolution of other traits, others (e.g., Pinker, 1994) claim that language evolved by the same kinds of natural selection processes as, for example, the visual capacity in order to meet specific needs of the human species.

Also falling into the category of a broader conception of the philosophy of language is the discussion about the degree to which the mind is modular. The modularity hypothesis states that the mind is not seamless but rather contains, perhaps alongside some general-purpose structures, a number of distinct, separate, domain-specific modules. According to Fodor (e.g., 1989) and others, one of the modules of the mind is dedicated to language, and its operations are insulated from the processes of cognitive domains lying outside the language module. A different approach to language processing is taken by connectionism, which embodies some of the principles of neural information processing. Connectionist models envisage states of knowledge as being constituted of degrees of connection strength between units rather than of rules or patterns, so that what is stored is not a set of patterns but rather “the connection strengths between units that allow these patterns to be recreated” (McClelland, Rumelhart, and Hinton, 1986, p. 31). Because of its incorporation of the notions of interconnectivity, parallel distribution, and spreading activation in processing, connectionism has been generally interpreted as antipathetic to the Fodorian conception of the language faculty.

Probably the two most salient trends in current linguistic philosophy are contextualism (see e.g., Travis, 2008) and semantic minimalism (see e.g., Bach, 2006). The contextualist perspective states that the mere literal meaning of a sentence does not correspond to a complete proposition with truth conditions, so that an appropriate linguistic understanding of an uttered sentence relies on the invocation of contextual and background knowledge. Semantic minimalism claims that, on the contrary, utterances of a given sentence share a minimal semantic content: the proposition semantically expressed.

None of the foregoing specifically addresses multilingualism, still less the multilingualism of the present era. For philosophers such as Spengler every philosophy gives expression to its own time alone, and each dispensation requires its own philosophical framework—a perspective which clearly implies that the new realities of current multilingualism pose a philosophical challenge. The remainder of this entry sketches a characterization of a philosophy of multilingualism which might begin to respond to this challenge.

Defining the Aims and Subject Matter of a Philosophy of Multilingualism

A large number of academic subjects have developed a philosophy around them; one thinks, for example, of the philosophy of science, the philosophy of mathematics, and the philosophy of history. It is clear that multilingualism studies, as an academic subject which embraces all fields connected with language and which focuses on a dominant, almost

defining, trait of the current human condition, ought to be a prime candidate for attracting a philosophical monitoring operation.

Whereas linguistic philosophers have traditionally asked questions about the nature of language and its relationship to meaning, concepts, and reality, a philosophy of multilingualism would address not only language itself but also the acquisition and use of two or more languages, the environments of such acquisition and use, and the associated patterns and imperatives.

Some relevant questions already being posed within multilingualism studies include the following.

- What does it mean for a particular code (a) to be called a language or (b) to be treated as a subcategory of a more widely used language? Thus, is Bayerisch, the language variety (or rather the spectrum of language varieties) in use in Bavaria, a language or is it a “dialect” of German? Are people who use Standard German, Bayerisch, and English bilingual or trilingual? What arguments are to be used in answering the above questions and what is the significance of particular responses to them?
- Is there a substantive and qualitative (rather than simply quantitative) difference between bilingualism and multilingualism? If so, what is it? Is the relationship between bilingualism and multilingualism a generic-specific connection? If so, is bilingualism superordinate to multilingualism or vice versa? What might the impact of different answers to such questions be in theoretical and practical terms?
- What philosophical consequences flow from the fact that most inhabitants of our planet are not monoglots? How does it relate, for instance, to proposals from Humboldt, Sapir, Whorf and others regarding the construction of an individual’s or a community’s *Weltbild*?

The Future

A basis of interaction between philosophy and multilingualism studies is indicated by the fact that the latter already make use of concepts long familiar to philosophers: *inherent qualities*, *relativism*, *determinism*, and so on. Likewise, *cognitive notions* which figure in the purview of philosophy, such as *belief*, *understanding*, *reason*, *sensation*, *perception*, *intuition*, etc. also figure in multilingualism research.

With regard to different branches of philosophy, *epistemological* discussion could, for example, fruitfully focus on the complex nature of multilingualism and the feasibility of encompassing this complexity, and *metaphysics*, in its role of explicating objects of interest, could turn its attention to entities and data associated with multilingualism and multilingualism studies—multilingual minds, multilingual persons, multilingual universals, etc. The insights of *ethics* could be brought, furthermore, to bear on decisions regarding language policy, language planning, and language education under multilingual circumstances, which relate, for instance, to the allocation of official status to languages, standardization and the specification of norms of usage, the distribution of resources for different languages, and the selection of curricular and vehicular languages in education. There are also ethical issues generated by the global spread of English and connected issues associated with the maintenance and revival of endangered languages. Challenges that arise in this context include the balancing of individuals’ rights against the rights of languages, and the assessment of political and moral value judgments relative to languages and cultures.

With regard to the possible input of multilingualism studies to philosophy, a multilingual perspective could, for example, substantially change the nature of discussion of recent contributions to the philosophy of language deriving from nativist, modularist, connectionist,

contextualist, and minimalist proposals. One thinks in this context, for instance, of the manner in which the empirically based notion of multi-competence (see e.g., Cook, 1992) has transformed earlier quasi-philosophical conceptions of language competence.

In short, the realities of multilingualism, both as experienced in daily life and as illuminated by research, need urgently to be put in touch with higher-order thinking.

Multilingualism and the Internet

SIRPA LEPPÄNEN AND SAIJA PEURONEN

Introduction

Why multilingualism and the Internet should be an interesting and important topic at the present time (2011) has a great deal to do with globalization. The Internet is a mass medium enabling the global dissemination of information and communication between geographically distant individuals and groups. At the same time, for many people—migrants, diasporic, and (sub)cultural groups, for example—it functions as a niche medium, providing them with a shared space for transnational or translocal activities (Block, 2004; Leppänen, Pitkänen-Huhta, Piirainen-Marsh, Nikula, & Peuronen, 2009; Leppänen, in press) in which processes of globalization contribute to language choice and the use of multilingual repertoires which can combine a variety of linguistic and semiotic resources (Blommaert, 2010, p. 7). At the same time, such globalization processes of the Internet as these have also heightened concerns that the future of the Internet is not, in fact, multilingual, but monolingual, with English as the dominant vehicular language of communication (see e.g., Crystal, 2001).

Multilingualism on the Internet refers to two interrelated phenomena (see also Androutsopoulos, 2006). First, it can mean the choice and diversity of languages as means of communication and analyses of their visibility, accessibility, and status on the Internet (Wright, 2004; Danet & Herring, 2007). In focus here are such language political questions as how much and for what purposes different languages are actually used online, whether or not their distribution reflects linguistic diversity in the world in adequate ways, and whether globally or regionally powerful languages are threatening to replace other (smaller or minority) languages in online settings. Thus, investigations of this type of multilingualism are often concerned with the protection and revitalization of lesser-used languages on the Internet. In this conceptualization of multilingualism, the Internet is seen as reflecting the language situation of the world offline, as well as a language political agent which has a great deal of power to influence the linguistic preferences and uses of individuals, groups, institutions, and societies. In other words, what happens to languages online is taken to have repercussions on the language situation offline, and vice versa.

Second, multilingualism on the Internet can refer to Internet users' ways of selecting, drawing on, and using of more than one language in particular modes and environments of computer-mediated communication (CMC) whereby they can seek to achieve their situated or sociocultural goals in contextually and communally appropriate and meaningful ways. Importantly, often such uses are not simply an outcome of the Internet users' bi-/multilingualism. Rather, they may be a manifestation of their orientation to using all the semiotic resources available to them, including those provided by more than one language—of their *metrolingualism* (Otsuji & Pennycook, 2010) or *polylingualism* (Jørgensen, 2008). In many Internet settings this poly-/metrolingual orientation is also accompanied by intralingual and discursive *heteroglossia* (Leppänen, in press), whereby Internet users make use of not only more than one language, but also diverse resources provided by intralingual registers, varieties, styles, genres, and intertextuality.

Defining the Internet

Before launching on a more detailed discussion of these key issues, it is first, however, necessary to define what we mean by the Internet itself. This is because the Internet is, in fact, “an ambiguous term referencing or encompassing innumerable technologies, uses and social spaces” (Markham, 2008, p. 454). It not only refers to the World Wide Web, but also to other information and communication systems outside the Web, such as e-mail, forum discussions, newsgroups, bulletin boards, instant messaging, chat, and Web (phone) call systems.

These different formats of the Internet have made possible a range of synchronous and asynchronous communication modes, some of which are interactive (e.g., discussion forums, different types of chat) while others are more text based (e.g., blogs, fan fiction). Furthermore, in many of them (e.g., YouTube, Myspace, Flickr), not only text, but also multimodality—visual effects, pictures, moving images, and sound—serve as means for sharing information and for engaging in cultural production and social interaction. The different formats and technologies establish, in fact, a complex web of media which have become increasingly interconnected and convergent so that one device can, for instance, combine characteristics of several media, for example the computer, television, and telephone. Within this networked mediated space individuals and groups have a great deal of choice as to the kind of communicative space, mode, and style in which they operate.

Different Internet settings and communicative modes thus constitute quite different environments for language use and require from users the mobilization of sometimes quite distinct register and genre features. Bearing the complexity of the notion of the Internet in mind, it is important that researchers specify what kind of communicative environment they are working on and contextualize their findings in relation to the technical, discursive social and cultural parameters of these environments.

Different Ways of Using the Internet as a Source of Multilingual Data

As a source of multilingual data, the Internet has meant a range of things to scholars, depending on their respective fields. As in linguistic research on the Internet in general, in the study of multilingualism online a few basic orientations can be identified. First, in some studies the Internet itself is treated as a massive pool of data representative of the language(s) used in it. In such studies, the aim typically is to discover and describe language facts, for example for the purpose of monitoring language variation, innovation, and change (see e.g. Crystal, 2001). Second, there are studies which have used the Internet as a basis for the compilation of a large and balanced corpus of either of particular Internet genres (such as e-mail, or blogs) or of the whole of the Internet (Kehoe & Gee, 2007) for the purpose of exploring general and quantifiable patterns of language(s). Third, the Internet has also been used as a source of discourse data. In this type of research the data collected is seen to represent particular situated language uses shaped by a number of contextual parameters (such as the participants and goals of the discourse practice). Such studies typically aim for close qualitative analyses ranging from, for example, ethnographic investigations of Internet users’ multilingual practices, to analyses of patterns of language use (e.g., code switching), to analyses of the ways in which more than one language is mobilized in the construction of some pragmatic, sociolinguistic or real world issue (e.g., identity or power), and to studies focusing on the ways in which the Internet itself creates affordances for and constrains particular kinds of language uses (for an overview, see Leppänen & Peuronen, in press).

Paradigms of Research on Multilingualism on the Internet

The fact that the Internet is a central and meaningful forum for language use and communication for a growing number of individuals globally poses an important challenge for language studies. More studies are needed to understand and explain the ways in which Internet users select their language of communication, and make use of multilingual resources in their activities, and to discuss the implications of language uses with respect to, for example language policies and language education. Despite the fact that the study of multilingualism on the Internet is still to a large extent emergent, it is already possible to identify some paradigmatic research orientations within it—these will be briefly discussed next.

Macro-Sociolinguistic Studies of Language Choice and Diversity in the Context of the Internet

Studies with a macro-sociolinguistic orientation to multilingualism have sought to find out what languages, language varieties, and writing systems are being used online. In this type of research a fundamental premise has been that the quantity, visibility, and accessibility of a language on the Internet are important safeguards of its vitality and importance.

Research of this kind is illustrated by studies which aim to assess the amount and types of linguistic diversity online. For example, a set of studies commissioned by the United Nations Educational, Scientific and Cultural Organization (UNESCO) (Wright, 2004) surveyed attitudes of students of English in 10 countries to find out their language repertoires and which languages they used when engaging in different activities on the Internet (Kelly-Holmes, 2004, p. 66). In these studies, the role of lesser-used languages on the Internet was discussed along with considering the possibilities for language revitalization by means of the Internet. In addition, the studies addressed the question whether and in what ways English may pose a threat to other languages used online. The survey indicated that there is a digital and linguistic divide between Internet users in richer and poorer countries, manifesting not only in the different degrees of Internet accessibility (see e.g., Mafu, 2004), but also in the amount of resources available to provide services in local languages. For example, in poorer countries Internet users rely on English-medium sources whereas users in richer countries are able to access information in their own language (Kelly-Holmes, 2004).

In another set of studies commissioned by UNESCO, an attempt was made to develop reliable methods for measuring the linguistic diversity on the Internet and, in particular, the actual proportion of the use of English in relation to other languages (Pimienta, 2005, p. 33). On the basis of these studies, it was argued that the linguistic diversity of the world is not adequately represented on the Internet and that the Internet favors large languages (particularly English) and the technical standards associated with these (Paolillo, 2005, pp. 54–5, 79). However, it was also argued (Paolillo, 2005, p. 55) that in reality it is difficult to predict the effect of the Internet on small and minority languages: it may lead to their weakening—as the status of larger languages is consolidated online—or to their strengthening via the visibility, accessibility, and appreciation they may gain when they are used on the Internet.

Evidence provided by measurements of the linguistic situation on the Internet have often led to attempts to document and advocate the use of the Internet to archive, promote, and teach small, minority and endangered languages (Warschauer, 1998). Such initiatives can be very important in raising awareness and increasing the appreciation of small or endangered languages, but their success often critically depends on whether or not speakers of the lesser-used languages themselves have access to the Internet and, if they do, whether

they are committed to actually using its resources to maintain and revitalize their language (Mafu, 2004; Sperlich, 2005; Androutsopoulos, 2006, p. 429).

Describing and Explaining Language Choice and Multilingual Language Uses on the Internet

For many people the Internet has become a translocal linguistic contact zone in which multilingual resources and repertoires can turn out to be crucial capital for successful communication, action, and interaction (Leppänen, in press). For researchers, the rise of such a conceptualization of Internet multilingualism in the early 2000s has meant a shift from measuring the online presence of global and other languages to the investigation of the Internet as a space for language practices (Androutsopoulos, 2008) which are simultaneously rooted in and voicing the local, as well as responding to and appropriating the global (Leppänen et al., 2009). For example, in many international and local social media environments which focus on topics or interests relating to some aspect of popular culture as a globally shared frame of reference (e.g., football, pop music, films, and TV series) such a translocal orientation is very evident. In this area of research the focus is on the specific multilingual practices, preferences, and policies of Internet users, the motivations behind their language choices, and the functions and meanings their language choices and uses have for them in the specific Internet contexts in which they operate. What such language practices call for is research which can help us understand and explain them as situated and socioculturally meaningful action; research that stems from, for example, the discourse analytic, ethnographic, pragmatic, and micro-sociolinguistic traditions.

In such investigations of computer-mediated discourse, identity and sociocultural practice have often proved to be important explanatory perspectives. Multilingual resources have been shown to be part of the indexical means through which identities and a sense of shared social world can be constructed and negotiated, contested and policed (Leppänen, 2009; Kytölä, in press). For instance, it has been shown (Androutsopoulos, in press-a) how participants can signal their interpersonal relations and alignments through code switching and style shifting between social varieties.

The ways in which Internet users' language practices contribute to the establishment and negotiation of affinity spaces or communities of practice with shared cultural and social conventions have also been investigated in ethnographic studies. They have analyzed online activities either alone or complemented by fieldwork in offline settings in which also the participants' Internet uses are examined with the help of, for example, surveys, interviews, and observations (Androutsopoulos, 2008). Such multidimensional ethnographic investigations can prove particularly useful in helping to explain the ways in which Internet users themselves make sense of and account for their engagement with the Internet and the affordances it offers them for meaningful social and cultural action (e.g., Nikula & Pitkänen-Huhta, 2008).

Multilingual Language Settings on the Internet

When analyzing multilingualism on the Internet, it is important to bear in mind that there is not just one, but several possible language settings in which more than one language may be used. One particular language setting is the kind in which participants have *no shared language*. Consequently, they need to choose a vehicular language which they can relatively safely assume that the other participants also know and are able to use in communication. For this purpose, English is often a self-evident choice. For example, it has been shown (e.g., Wodak & Wright, 2006) how in multilingual Internet networks the

participants favor English as their shared language because it ensures the widest possible understanding among the participants.

Another typical language setting in which participants in CMC often operate multilingually is one in which they choose *some other language than their L1 as either the primary communicative code or as an additional resource alternating and mixing with their primary language*. However, in such a setting, the motivations for their choice of language can vary a great deal. Sometimes the language choice online is an extension of the participants' offline language preferences and uses, but it may also be the outcome of an official language policy or grassroots, group-specific language policing online (Leppänen & Piirainen-Marsh, 2009). Such language policing is often evident in not only the participants' particular language choice but also in the ways in which they orient to and monitor choices by others. For example, there is evidence from different countries (see e.g., Warschauer, Said, & Zohry, 2002; Androutsopoulos, 2006; Siebenhaar, 2006) that in more spoken-like and dialogic Internet environments, in discussion forums and different types of chat applications, for example, when participants choose to use a language other than their L1 language, vernacular varieties tend to be preferred over standard or formal varieties. In addition, such a language choice can be a sociocultural index; for instance, in Web discussion by Finnish football fans (Kytölä, in press) their choice of Finnish, English, or Swedish at different points of their discussion can effectively cue their varied stances toward the topic under discussion and their co-conversationalists.

Sometimes participants in CMC can draw on resources provided by several languages to such an extent that the outcome is thoroughly heterogeneous discourse. For example, it has been shown how interactional computer-mediated discourse (e.g., forum discussions) can be eclectic, creative, and dynamic in the way they adopt, adapt, and appropriate available forms and patterns from more than one language to serve particular communicative purposes and contextualize meanings in their interactional context (Androutsopoulos, in press-a; Peuronen, in press). In a similar vein, studies of writing in Internet genres such as blogs or fan fiction have shown how drawing on resources from several languages is part of a more general heteroglossic repertoire of stylistic, intertextual, and narrative resources which can be used by writers to craft contextually meaningful and socially appropriate texts (Leppänen, in press).

Multilingual Internet Discourse as Heteroglossia

In the investigation of many informal multilingual Internet genres which often are not only linguistically but also discursively heterogeneous, the concept of heteroglossia can serve as a heuristically useful tool with which to unravel and explain their complexity (Leppänen et al., 2009; Leppänen, in press). As originally defined by Bakhtin (1981, p. 291; see also Bailey, 2007; Androutsopoulos, in press-b), heteroglossia refers to discourse which combines and mixes forms and content that represent "the co-existence of socio-ideological contradictions between the present and the past, between differing epochs of the past, between different socio-ideological groups in the present, between tendencies, schools, circles and so forth." In focus in heteroglossia are thus not only the co-occurrence of and shifts between languages or language varieties, but also how language uses index ideological points of view, including links and tensions between these, and engage with larger social, historical, and ideological processes.

More specifically, the notion of heteroglossia makes it possible to identify different aspects of linguistic heterogeneity. First, it helps to identify and distinguish between the selection and combination of resources from more than one language and *intralingualism*, the selection and combination of features from more than one variety, register, or style of

a language. Second, heteroglossia allows the identification of two types of multilingual heterogeneity. One of these is a *mixed in-group style* in which Internet users orient to and make use of the linguistic resources available to them, no matter which language they may technically be associated with (see also Jørgensen, 2008; Otsuji & Pennycook, 2010). Another aspect of multilingual heterogeneity is *code switching*—one of the semiotic resources available to Internet users to contextualize, highlight, or to make relevant possibilities for the interpretation of discourse and reality within a discourse entity. Finally, heteroglossia can also entail a *discursive dimension*: the selection, combination, and juxtaposition of discursive resources, for example, aspects of genres, modalities, and intertextuality (Leppänen, 2009; Leppänen & Piirainen-Marsh, 2009) within a discourse entity. For example, in blogging or fan fiction discursive heteroglossia can play a key role in writers' efforts to create the kind of generically and intertextually complex and multi-layered discourse that is prized by their respective communities of practice.

Multilingualism on the Internet and Language Learning

Despite the doubts that many parents and educators have about the usefulness and value of young people's online activities, the fact that many of them operate on the Internet multilingually can have a great deal of potential in terms of first-, second-, and foreign-language learning. One reason for this is that for many young people Internet-based peer-focused communication can provide stimulating opportunities for informal learning—possibilities for the recognition, application, and practice of patterns of language and discourse, aspects of new literacy, and forms of interaction for purposes of authentic communication, social life, and cultural production (e.g., Leppänen & Piirainen-Marsh, 2009). In addition, in many Internet activities which involve planning and design—such as fan fiction writing—participants have developed resources and services which are in principle instructional, teaching novice participants, through feedback, commentary, and explicit sets of instructional materials, appropriate ways of language use in the particular Internet genres their writing inhabits (Leppänen, 2009).

In recent years, a great deal of research interest has shown in the pedagogic potential of young people's Internet-based activities (see e.g., Lam & Rosario-Ramos, 2009) and pedagogic experimentation relating to the uses of technology in second- and foreign-language classrooms (for an overview see, e.g., Thorne, Black, & Sykes, 2009). These studies have argued strongly for the necessity of a renewed vision of educational practice that would harness the potential of communicative technologies in language instruction and suggested ways in which language learning can be enhanced by, for example, the use of digital vernacular texts in education (Thorne & Black, 2007).

However, while the Internet, or more generally, digital information and communication technologies, can offer new incentives, opportunities and activities for language learning, it may be that for many young people the integration of their out-of-school Internet activities within school-based language instruction can be problematic. One reason for this is that their Internet activities are part of their own lifeworld, and a forum of social life outside the control and agendas of the adult world, parents, and teachers. As a result, teachers wishing to make use of young people's online interests and activities in language teaching may sometimes face the resentment and reluctance on the part of their students. On the other hand, the recognition of the linguistic and discursive expertise that students may have and its sensitive use as a means to scaffold opportunities for further language learning in a way that does not intrude too much into young people's own cultures on the Internet, can be an effective strategy to empower students and enhance their language learning.

Conclusion

This entry aimed at outlining how multilingualism on the Internet can mean a variety of things, depending on how the notion of the Internet is conceptualized, which genres and modes of communication (e.g., edited webpage contents vs. interactive CMC modes) or language settings are focused on, and the disciplinary perspective from which their analysis is approached. It also aimed at illustrating the emergent paradigms of current research on multilingualism on the Internet. One of these was labeled the macro-sociolinguistic approach, and it was shown to be concerned with assessing the degree of linguistic diversity online, evaluating the threat posed by English as a popular vehicular language to other (smaller, minority) languages in the world, and using the Internet as an instrument and forum in language maintenance and revitalization. Another central research paradigm was shown to focus on the study of the multilingual discourse practices of Internet users in different modes of communication, drawing on concepts and microanalytic methods provided by, for example, discourse studies, pragmatics, interactional sociolinguistics, linguistic anthropology and ethnography. The entry also described some of the crucial features of multilingual Internet discourse, and suggested that often it can usefully be anatomized with the help of the notion of heteroglossia which allows the identification of not only of different types of linguistic heterogeneity, but also of discursive heterogeneity.

The present overview of this emergent and multifaceted field of the study of multilingualism on the Internet is necessarily cursory, and many crucial issues could only be touched upon here. However, it needs to be emphasized that the multidimensionality of Internet multilingualism, which is only now beginning to be recognized in research, profits from investigations which approach it from a variety of perspectives and methodologies. These can help shed light on not only the specificities of but also the interconnections between language uses on- and offline, and on the functions and meanings of these language uses in the varied, but increasingly convergent linguistic, communicative, and discursive spaces of the Internet. Understanding the complex ways in which multilingualism works on the Internet, how and why Internet users make use of more than one language, is particularly important for applied language study. Research on Internet users' language practices can help us understand how language choice and linguistic (and discursive) heterogeneity are drawn on as semiotic and sociocultural resources. Understanding such motivations, goals, forms, and meanings of multilingualism on the Internet can thus help us define and formulate, for example, language policies when such policies are needed to protect and revitalize languages under threat and educational visions that can profitably build on and develop people's multilingual practices and that in turn can lead to learning, empowerment, and agency.

Multilingualism at Work

BRITT-LOUISE GUNNARSSON

The conditions for workplace discourse have been influenced by a series of changes taking place in recent decades. Throughout the world, we find transnational companies which use English, or another global language, as their corporate language and employ multilingual people who can move between jobs, between branches, and between countries. The workforce mobility and workplace diversity which characterize a globalized economy raise issues of multilingualism and multiculturalism to the surface, in relation both to the organization as a whole and to workplace practices. Technological advances have facilitated a globalization of working life and also changed linguistic practices at work. In today's economy it is not only managers and elite staff who need to be linguistically flexible; factory-floor workers also come in contact with different languages and different varieties of a language. They have to be prepared to interact with group leaders and fellow workers with a linguistic background different from their own. This entry focuses on multilingualism at work and will discuss a number of studies which explore discourse-related problems facing managers and employees in the globalized economy.

Workplace Discourse and Its Contextual Frames

The model presented in Figure 1 aims to grasp the complex and dynamic interplay between workplace discourse and its various contextual frames (for a more detailed presentation, see Gunnarsson, 2009, pp. 20–7).

Text and talk at work can be described as related to different situated communicative events. An in-depth analysis, however, must also include the macro level, that is the environmental framework in which the communicative events, or chain of events, occur. Text and talk in a small, close-knit working group with its particular social and communicative order therefore form part of traditions that evolve within an environmental structure: The small working group is included in a larger unit such as a workplace, which in turn belongs to a local branch of a large organization. In many cases, we further find additional organizational levels, for instance when the organization belongs to a corporation.

What also characterizes professional discourse is its dependence on various societal framework systems, such as a technical–economical framework, a legal–political framework, a socio-cultural framework, or a linguistic framework. We know that technology and technological advances are important for the dynamism within organizations of various kinds, as are the economy and economically driven changes. It is also self-evident that professional discourse is constrained by politics, laws, and regulations at local, national, and supranational levels. Professional discourse is also constrained by a socio-cultural framework system; ethical codes adopted in a particular professional environment thus reflect, to a large extent, ideologies and ethics in this framework.

In addition, professional discourse is dependent on the linguistic framework. The local language community, the national language community, and the supranational or global language community establish and follow language laws and policies which directly or indirectly influence text and talk in the professions. Language choice and language practice in professional environments follow, to a large extent, the practice in the relevant

Figure 1 Model of workplace discourse and its contextual frames. From Gunnarsson (2009)
© Continuum. Reprinted with permission.

discourse communities. Policies and practice on language-dominance issues (local language vs. global language; majority language vs. minority language), functional language stratification (diglossia), and social language stratification (elite and nonelite languages) formed within the various levels of the linguistic framework influence communicative events for professional purposes in terms of language choice and practice. The language knowledge and language use of the participants in a professional encounter, whether professionals or nonprofessionals, reflect language politics and laws.

Organizational Policy and Workplace Discourse

In order to understand multilingualism at work, it is relevant to make a distinction between organizational policy and workplace practice. Although bilingual and multilingual individuals have been and still are found in companies and organizations all over the world, many large organizations uphold an idea of linguistic unity. For practical and ideological reasons, large organizations often choose one official, corporate language. This language is used as a *lingua franca* (see Meierkord, 2007) in meetings and written communication; it also functions as a symbolic expression of an organizational unity. In many cases, the official or corporate language penetrates the whole organization, which means that all employees are assumed to master this language. The individual employee can thus be both bilingual and multilingual, as long as he or she masters the official language of the organization. In other cases, the official language is an elite language used at top-level meetings and for external, international contacts. The whole organization is then bilingual or multilingual, even though the majority of employees might be monolingual.

The organizational policy can mean that one language is declared to be the official language. This policy is then, for instance, seen in the language of major documents, such as annual reports, major contracts, company presentations, and messages to top-level staff. Other texts which reveal the language policy of a company are job advertisements. The company has to choose a language for their job advertisements but also make explicit which languages they require for staff in different positions.

Gunnarsson (2009, pp. 227–30) presents a study of the explicitly stated language requirements in advertisements for jobs in Sweden. A total of 100 job advertisements posted on the career-oriented pages of five transnational companies, which all operate in Sweden, were studied, namely AstraZeneca, ABB, Electrolux, Ericsson, and Scania. Swedish is the main official language in Sweden, and not surprisingly 63 of the 100 advertisements were written in Swedish. However, 32 were in English and 5 were in both Swedish and English (in fact mixing the two languages). If we look at which languages were stated as qualifications for the jobs, English was mentioned in all of Ericsson's and Electrolux's advertisements, while the proportion for ABB was 80% (21 out of 27), for AstraZeneca 60% (13 out of 23), and for Scania 40% (9 out of 23). Swedish is also stipulated as a qualification for employment in many of the advertisements, namely in 34 of the total 100. As all Scania's advertisements were written in Swedish, it was maybe less surprising that only 2 of their 23 advertisements mentioned Swedish as a requirement. More surprising, however, is that only 1 of the 13 advertisements written in English for jobs in Sweden at AstraZeneca mentions Swedish.

Swedish and English are thus frequently required languages for these jobs in Sweden. An interesting question to ask is of course if other languages were also mentioned in the advertisements. On the whole the answer to this question is that languages other than English and Swedish are required to a very limited extent. Of the 100 analyzed advertisements, only 10 required other languages. It should also be noted that these other languages are mentioned together with English and Swedish: The company seems to wish to hire Swedes with language skills in English and one other foreign language. The other languages in question were Russian, German, and Spanish.

The Multilingual Workplace

In today's global and virtual economy, we do indeed find bilingual and multilingual professionals in top positions: as engineers, managers, technicians, doctors, university professors, or sportspeople. As many studies of intercultural communication have shown, we also find businesspeople throughout the world who are able to strategically use a language that suits their needs and their business partners (Firth, 1995; Poncini, 2003; Breckle, 2005). In multilingual areas, such as Luxembourg, Switzerland, and Brussels, we further find staff in many service-oriented enterprises—banks, assurance companies, travel agencies, railway ticket offices—who are able to flexibly shift to a language that works for their customers (Bothorel & Choremi, 2009; Kingsley, 2009; Lüdi, Barth, Höchle, & Yanaprasart, 2009; Mettewie & Van Mensel, 2009).

Studies of Workplaces Using English as a Lingua Franca

In recent decades, several applied-linguistics studies have analyzed new mergers and transnational companies which have chosen English as a lingua franca (e.g., Nickerson, 2000). Among these are found a series of studies exploring two Scandinavian mergers. For people in the Scandinavian countries, English is the first choice of language at an international level: Swedish, Danish, Norwegian, and Finnish are not understood outside Scandinavia, which creates a need for a global language in external communication. In the

last decade, English has also come to be used as an internal common language in Nordic mergers, for instance in the Finnish–Swedish company Stora Enso and in the Finnish–Swedish–Danish bank Nordea. Kankaanranta (2005, p. 42) describes the new type of communicative practice in the following way:

In practice, this language choice means that corporate-level documentation and all reporting is done in English, and communication between different units is mostly in English. This type of communication can be characterized as internal communication as it is taking place “in-house” in contrast to communication between buyers and sellers in which foreign languages have been traditionally needed in international business. For an individual writer of an email message, the choice is a pragmatic one: anytime there are recipients whose mother tongue is not that of the writer’s, the message is in English. This means that a Swede (or a Finn) will receive an English message from another Swede (or a Finn) if the list of recipients includes non-Swedish speakers.

In her analysis of e-mails written in English by Swedish and Finnish employees of Stora Enso, Kankaanranta examined what the messages share, how they differ from native speakers’ messages, and how the messages written by Finnish writers differ from those written by Swedish writers (2007, p. 480). E-mail messages written by both Finns and Swedes differ from native English speakers’ messages in the frequent use of salutations and complimentary closes together with first names. By using these phrases, which reflect ordinary letters, the employees create and maintain personal relationships within the company, at least according to Scandinavian conventions (p. 461). As regards differences between the Swedish and Finnish writers, the analysis revealed how Finns seem to favor direct requests in their writing, while Swedes use more indirect alternatives.

Similar cultural differences were also found in studies of spoken interaction (Charles & Louhiala-Salminen, 2007). Kangasharju (2007) compared results from interviews with video-recorded internal meetings. The meetings were either national meetings held in Finland or Sweden, or cross-border meetings where Finns and Swedes met, using English as a *lingua franca*. A difference stressed in the interviews concerned the amount of time allowed for discussion and the chair’s efficiency (i.e. his or her orientation toward decision making). Swedish meetings were said to involve long discussions loosely steered by the chair, while Finnish meetings were said to be shorter and focused on the decisions to be taken. The analysis of the meetings both confirmed and questioned what had been said in the interviews. At the national meetings, there was a clear difference between Swedes and Finns. At the cross-border meetings, however, the cultural differences seemed to be of minor importance. As the language at these meetings was a second language for both Swedes and Finns, new practice had developed, for instance a new way to control that everyone had understood what was decided (Kangasharju, 2007, p. 372).

Nikko (2007) also analyzed Finnish–Swedish interaction in the mergers. Although the main language of the internal meetings recorded was English, code switches were common in all meetings, which meant that, besides English, Finnish and Swedish were also used. As all participants were either Finns or Swedes, code switching seemed to be a natural tool to use to overcome language shortages (p. 409). On the whole, the creation of meaning in the meeting interaction appeared to be highly successful, a fact which Nikko attributes to “the participants’ strong commitment to common goals,” “the informal and relaxed nature of the communication,” and “the vast amount of shared background information and shared experiences of the participants” (p. 478).

Following these studies on workplace settings where all participants turn to English as a *lingua franca*, studies which explore interaction involving native English speakers will also be discussed. Jämtelid (2002) reports on interviews with people involved in writing

at different levels of the Swedish Electrolux group. Electrolux had chosen English as its corporate, official language. A widespread belief among managers and staff at the time this study was made was that native speakers of English found their corporate English poor. The point to be stressed here, however, is what the director of corporate communications said about interaction with native English speakers. He elaborated on the difficulty facing English lingua franca speakers in contexts where some participants are English native speakers, as well as on the necessity for Scandinavians to speak up even if their English is bad (Jämtelid, 2002, p. 44):

Then of course the corporate language is quite clearly "bad English". Otherwise, you easily end up with only Americans, Brits and well-educated Swedes talking at meetings, while Germans and Italians remain silent. What happens, rather, is that we deliberately avoid difficult words, and that people shouldn't feel ashamed at all if they use bad grammar in an internal memo in English. (my translation)

When Franklin (2007) interviewed German and British managers who worked together in a newly established German-British company, he found that the German managers mentioned the native English speakers' lack of lingua franca skills as a perceived difficulty:

The German managers reported that their British colleagues were unable or unwilling to take account of the fact that they (the German managers) did not have a native-speaker competence in English and did not adjust their use of their mother tongue to the lower level of competence in English of their German colleagues. For example, one German manager noted of his British colleagues: "The English aren't always sympathetic to Germans when they speak English. To begin with, the English speak slowly, but then fall back into speaking the same speed and slang as if the listener is a native." (p. 273)

Studies of Workplaces with Workforce Diversity

Looking at multilingualism at work from a work-floor perspective, we do, of course, find second, third, and fourth language users in many low-status jobs. As Roberts (2007a, p. 405) writes, the settings where migrant workers have found jobs are shop-floor and service-industry settings, including the health service. This means that their status and work identity have been constructed not by their educational and background qualifications but by gaps in the labor market; a teacher may be a postal worker, a farmer may be a factory worker, a doctor may be a care assistant.

All over the world, there are workplaces where some employees, mostly minorities, migrants, or unskilled guest workers, have to use their second, third, or fourth language at work. In a questionnaire given to people in Europe in 2000, 15% of respondents reported active use of a second or third language in their workplace (Day & Wagner, 2007, p. 395). This percentage, which relates to the European job market, might be low for other parts of the world. It might also be outdated, as the professional world is constantly undergoing change. Nevertheless, it is a fact that knowledge of the dominant local language is necessary not only for advancement and a career within most organizations, but also for social integration into the working group. In one way or the other, migrants have to adapt their linguistic behavior to that of the dominant group. Most often, they have to use the local majority language in their daily communication at work. In order to become a full member of the working group, the migrant also needs to find a way of participating in social communicative events. Humor, jokes, stories, and anecdotes form part of the workplace discourse and contribute to the establishment of friendship and collegiality at work and also to the avoidance of unnecessary conflicts. Social workplace patterns related to friendship, power, and dominance often reflect linguistic and communicative skills.

There is indeed a difference between regions where the majority language is a global language and those where the majority speak a less widespread language. We know that individuals who migrate to English-speaking countries have often learned English at school in their countries of origin. When they migrate to Australia, New Zealand, the UK, or the USA, they already have a basic knowledge of the majority language. Studies of workplace practice in English-speaking regions (e.g., Clyne, 1994; Holmes & Stubbe, 2004; Marra & Holmes, 2007) thus reflect a different linguistic framework from studies of workplaces where the majority language is a third or fourth language for the immigrants. In parts of the world, where less widespread languages are spoken, immigrants meet both a new country and a new language. For them, learning the majority language becomes a part of their adjustment to a new country and culture (Gunnarsson, 2005).

With this as a background, some of the results of a research project entitled “The communicative situation of immigrants at Swedish workplaces” will now be discussed. Using a similar design based in interactional sociolinguistics, Andersson (2009) studied a large hospital, and Nelson (2010) a major Swedish company. The first phase involved interviews with a fairly large number of immigrants: 18 at each workplace. The immigrants came from different parts of the world and had migrated to Sweden as adults. They had permanent jobs, although in different positions: at the hospital, the study included doctors, nurses, midwives, and cleaners, and at the company, office staff and factory-floor workers. All participants were second language users at work—both Swedish and English were foreign languages for them. The second phase involved case studies, five at each workplace. The employees were shadowed during a week, and data related to their workplace communication were collected.

In this section, a few results related to the language situation at the two working environments will be examined. At the hospital, communication with lay people—patients and relatives—forms an important part of the daily work of the medically trained staff (i.e., doctors, nurses, and midwives). This means that the majority language of the local community—Swedish—is the dominant language in their work. The doctors who were interviewed report that English is used in their research and in writing articles for publication. Some of the nurses also say that they use their mother tongue every now and then, which is neither Swedish nor English, since many patients come from their countries of origin. They then find themselves in the role of interpreter between patient and doctor.

The communicative situation for the cleaners at the hospital is very different from that of the medically skilled staff. When interviewed the cleaners say that Swedish is used when they speak to their managers, to hospital staff they meet when cleaning their areas, and to other cleaners when they do not have a common mother tongue. Many of the cleaners have very poor skills in Swedish, and since they mainly interact with others from the same countries, they do not get much practice in Swedish so their proficiency hardly improves, according to the managers who were interviewed.

In the company, communication is mainly directed to professionals—to colleagues linked to the same workplace or within the same organization or to other professionals. As the workplace studied belongs to a large, transnational company for which English is the corporate language, the language practices are of a diglossic nature. English is used as a *lingua franca* for external purposes, for instance in written correspondence with colleagues in other countries and in meetings with external professionals, while the local majority language, Swedish, is used for internal purposes and in the daily spoken interaction with colleagues.

From the point of view of language, a clear divide exists between office staff and factory-floor workers. When the office staff were asked about the languages they used at work, three out of nine said that they mainly use Swedish, three that they mainly use English, and three that they use English and Swedish to an equal extent. All claim that they write

English more often than they speak it. Two thirds of the office staff also say that they have used their mother tongues at work.

All factory-floor workers interviewed say that Swedish is the language they use at work. Although they say that they come into contact with English texts, they do not claim to read them. Only one third of the factory workers say that they have used their mother tongues in the workplace, whereas two thirds of the office staff have used their mother tongues at work. The office workers thus seem to use languages other than Swedish and English to a greater extent than factory-floor workers. They are more involved, for example, in guiding or taking care of groups and representatives from foreign countries than factory employees.

The communicative situations for the employees interviewed are thus different at the hospital and at the company, and also within each environment. As mentioned above, all informants have permanent jobs and they also seem to be able to perform the tasks they are assigned. Their position at work and the tasks they are given correspond to their linguistic competence and communicative skills. Lack of language skills therefore hinders promotion in both environments: At the hospital good Swedish is necessary for a career and at the company both English and Swedish are required. In the company good writing skills are also important for promotion. We thus find that language knowledge creates a divide between those who master the corporate language and those who do not, and also between those who master the majority language and those who do not.

Problem Areas for Future Applied Research

The conditions for professional discourse have been influenced by a series of changes taking place in recent decades. New technology, workforce mobility, and a globalized market with transnational companies have transformed many workplaces to multilingual settings. A goal for future applied research is to analyze the various “new” problem areas and try to sketch how difficulties could be overcome.

In the global economy, organizations have to strike a balance between local and global concerns as well as between economic concerns and social and societal values in order to be competitive and trustworthy (Gunnarsson, 2009, pp. 222–35). The challenge for large organizations is to find a balance in policy and practice between these various considerations. Important topics for future research would be to analyze how language and discourse in organizations and workplaces reflect this balance. How is linguistic and cultural diversity constructed in workplace discourse? Who is marginalized and who is made central through workplace discourse? What societal values are expressed in official documents and more informal discourse within organizations?

Another topic which would be worth looking into relates to the role of discourse for bottom-up influence. The physical distance between one workplace and another is a reality in large, global organizations, which indeed means that both top-down and bottom-up communication have to be less direct. A research question is whether this physical distance hinders bottom-up influence on the organization. By what type of discourse is democracy established—and hindered—in the “new work order”? How does the new worker get his or her voice through to the top management level? How does top management try to steer the shop-floor workers? What role does language difference play for patterns of influence?

Multilingualism in Economic Activity

FRANÇOIS GRIN AND FRANÇOIS VAILLANCOURT

Language in Economic Analysis

The interest in the links between multilingualism and economic activity is relatively recent. Up until the early 1970s, the use of different languages or variants of one language was generally seen as raising (in addition to linguistic questions) mainly sociological, and occasionally political or legal, issues. Along with the notion that linguistic processes are deeply embedded in social ones came the realization that economic activity could be seen as a “domain” in the sociolinguistic sense of the term, and that taking this domain into account is important to the understanding of the dynamics of language learning and language use. In addition, economic activity is a highly relevant locus in which to observe multilingual interaction.

However, the interconnections between these two spheres (the linguistic and the economic) are numerous and complex, making it necessary to open this discussion with a general overview. A convenient starting point is the concept of *language economics* (or *economics of language*), which

refers to the paradigm of mainstream economics and uses the concepts and tools of economics in the study of relationships featuring linguistic variables. It focuses principally, but not exclusively, on those relationships in which economic variables also play a part. (Grin, 2003, p. 16)

Language economics is mainly a way of looking at human experience through the prism of economic analysis. The latter is structured around the notion of scarcity (of material *and* symbolic resources), hence the need for choices to be made. Thus, the mere fact that languages are used in the context of economic activity does not per se give rise to language economics questions: Such questions arise if scarce resources need to be allocated as part of a process in which language also intervenes. For example, given a limited amount of time for language study, what should lead some speakers of language X to learn language Y rather than language Z? Or given a certain advertising budget and the freedom to use any language, in what language(s) should a company market its products in order to maximize profits?

The analytical paradigm of economics opens up a broad field of inquiry that is not limited to conventional “economic” variables, and this also holds in the economics of language (Grin, 1996, 2010), which branches out into issues such as language acquisition (e.g., Selten & Pool, 1991), language dynamics (e.g., Church & King, 1993), and the structure of language (e.g., Rubinstein, 2000). However, most of the questions it investigates arise from the presence of many languages, which is why much of the language economics literature turns to issues of interest in language policy, particularly status planning (Grin, 2003). The issue of “multilingualism in economic activity” (sometimes under the label of “language and economy”), therefore constitutes but a part of language economics.

Before proceeding further, let us mention the existence of other perspectives on the interconnections between the linguistic and the economic, such as linguists’ explorations

on how economic concepts may lead them to reexamine their own concepts (Coulmas, 1992; Keller, 1994), or their analyses of economists' discourse (Henderson, Dudley-Evans, & Backhouse, 1993).

Language economics in general may fall prey to an inadequate understanding of the epistemological principles of economics as a discipline. We shall only highlight two points here. First, because of its focus on human choices, language economics, while retaining the ambition of producing statements with general validity (rather than idiosyncratic, case-specific accounts) presupposes a duly *situated* vision of social actors who learn and use languages. Second, the goal of an economic perspective on multilingualism is not necessarily to "put a price" on languages or to "reify" them. Economists treat language in different, nonmutually exclusive ways, usually as a skill used for communication; or as a carrier of identity which may be the object of discrimination; or as a tool used and manipulated to acquire or retain power; etc. However, language itself is practically never treated as an "economic good," but rather as a factor used in the consumption or production of market or nonmarket, material or symbolic, commodities. In economic analysis, language is always positioned with respect to the goals pursued by social actors and the constraints under which they operate. It is then, in these different roles, fitted into economic analysis. The latter is usually, though not necessarily, expressed through mathematical or econometric modeling.

Defining Economic Activity

Most of the work of economists (in which "language" is hardly ever mentioned as an issue) is devoted to the study from a microeconomic or macroeconomic standpoint (see below) of consumption, production, and exchange, which together give rise to what is often called "economic activity"—as distinct from "economics," whose scope is, as we have seen, considerably broader.

Microeconomics is structured around three core themes. The first is the behavior of the individual who buys goods and services and supplies labor to firms. The second is the behavior of the firm, which produces goods and services using labor, coalescing into a theory of production expressed through production functions that link what is produced with the resources used for this purpose. The third is the study of market exchange, which unfolds differently depending on whether the markets considered are competitive, oligopolistic, or monopolistic. Microeconomics is therefore used to study the activity of specific agents or the behavior of specific markets.

Macroeconomics focuses on the relationships between economic "aggregates," such as "consumption" (of all goods and services), "production" (likewise), or investment (acquisition of capital goods across all economic sectors). The total value of production in a national economy in a given year generates a very widely known concept, gross domestic product (GDP). Some standard topics in economics (for example international trade, monetary economics, public finance, development) cut across the micro–macro divide and can be studied at either level.

The important point, however, is that across the near-entirety of the economics literature, "language" simply never appears in analytical models. The implicit assumption is that the economic forces at hand are so fundamental that they transcend language, with the twin implications that: (a) no matter in what language it takes place, economic activity will operate according to the same principles, with similar causes generating similar effects; and (b) linguistic diversity can, most of the time, be understood as a mere form of transaction cost, and that, as such, it poses no crucial analytical problem. Language economics, however, questions these two assumptions. In what follows, we review some of the most

important ways in which the diversity of languages influences economic activity.

Language Skills and Labor Income

The first empirical work by economists on the relationship between the language skills of individuals and their earnings appeared in the mid-1960s, when Canadian economists were asked to explain differences in economic status between Anglophones and Francophones. A similar approach has been used to explain earnings differentials between Blacks and Whites in the USA.

In this work, no difference was made between language and ethnic identity, which neglected the role of language as a communication tool. In the 1970s, attention was paid to this dimension of language with researchers treating language as human capital, defined as a stock of skills in the development of which agents can invest, and from which they can expect a rate of return in the form of higher earnings. Linguistic attributes, particularly second-language skills, could then be viewed as assets comparable to education in general or to specific skills like computer literacy. Since the early 1980s, linguistic attributes have been viewed as comprising both people's ethnic identity (usually represented by their mother tongue) and their linguistic human capital (usually, their competence in additional languages). Equations with earnings as the explained variables, and various control variables such as work experience or education level along with language skills, are computed using econometric tools to estimate returns to language skills wherever the availability of individual statistical data allows.

This empirical work addresses two types of issues. On one side, some research (for the USA, Australia, or Israel) investigates the role of competence in the locally dominant language in the determination of the respective socioeconomic status of immigrants and native-born workers (Chiswick & Miller, 2007). Unsurprisingly, English-language skills are found to be statistically significant determinants of labor income for immigrants to the USA. On the other side, a well-established Canadian tradition studies earnings differentials between Anglophones and Francophones and their evolution over time, taking account of people's skills in a language *other* than the locally dominant one. In the province of Quebec, where some 80% of residents have French as a first language, earnings differentials were significant (and in favor of Anglophones) well into the 1980s. Since then, the reverse is observed as well as a general premium to multilingualism (Vaillancourt, Lemay, & Vaillancourt, 2007). For example, by comparison with "unilingual Francophones," "bilingual Francophones" (that is, native speakers of French who are also fluent in English) reaped a wage premium of 12.2% (men) and 17% (women) in 2000. The focus of recent research, particularly in Europe, has increasingly been on the returns on the investment in foreign-language skills, including other official languages in multilingual countries such as Luxembourg or Switzerland. For example, the returns on competence in German and French as "foreign" languages, in the French- and German-speaking parts of Switzerland respectively, consistently fell in the 10–20% range across the country, while the returns to English range from 10% to 25% in 1995; higher percentages result from higher competence.

Language Preferences in Consumption

The relationship between earnings and language is not the only one that has been studied empirically by economists. Another issue is the choice of one or another language in consumption activities. This work focuses on bilinguals, who can choose between two languages. Generally, they will use one or the other depending on their preferences, values, and needs, and on the material and symbolic costs of performing various activities in one

or the other language. Early econometric work (Vaillancourt, 1985) found that for consumption activities among bilingual Francophones in Quebec, better knowledge of English was associated with a weaker preference for French. This result is obtained controlling for age, income, sex, and schooling.

The effects of the variables listed above are far from simple, and it can be shown that an increase in the income of bilinguals (such as native speakers of Welsh who also speak English) may have a positive or a negative effect on the use of either language. The outcome will depend on the interplay of a number of factors, including people's preferences for doing things in one language or the other (for example, spending leisure time with their children), the price of the goods needed to carry out these activities through one language or the other (for example, the relative price of children's books in English and Welsh), and the degree to which people can substitute goods for time when performing such activities. Theoretical modeling allows us to examine more precisely how these various factors interact (Grin, 1990).

Language and Macroeconomic Activity

The work examined above is of a microeconomic nature, focusing on individual outcomes or choices. But what happens in the aggregate, that is, in the language of economists, at the macroeconomic level? What share of output or value added stems from multilingualism in a given economy? This question has been addressed in recent work using data from Switzerland and Quebec (Grin, Sfreddo, & Vaillancourt, 2010). It requires identifying where multilingualism appears in the process through which value is created, or added to what existed before.

Value creation, as captured by a production function, is examined for the year 1995 for nine industries in Switzerland and, for the year 2000, for three industrial groups in Quebec. The contribution to output of various types of labor according to their language skills is estimated, and the results obtained used to calculate the effects of changes in the level of linguistic variables. The economic effects of "linguistic amnesia" can be simulated, showing what would happen to aggregate output in a sector or a country if the workers suddenly lost all of their second language skills (that is, if bilingual workers suddenly woke up unilingual). In the case of Switzerland, if Francophones forgot all their German and Germanophones all their French, then total output (GDP) would drop by 5.2%, while drops in sectoral output would range between 3.3% and 9.5%. If, instead, English-language skills vanished, then the overall drop in output can be estimated at 5.6%, ranging from 0.4% to 10.4% depending on the economic sector. In that case, the two largest drops are found in the hotel/restaurant and in the financial and business services sectors, sectors which are driven by demand from foreigners. In the case of Quebec, we find an overall drop of output of 3–4% if second language skills disappear, ranging from 2% for sectors with low use of language skills to 9% for sectors with high use of language skills.

Multilingualism and the Process of Value Creation

The existence of the statistically significant language-based earnings differentials discussed above calls for an explanation. When these differentials are linked to people's first language and hold even after controlling for their second language skills, they suggest the existence of language-based discrimination. But what explains differentials related to people's *second* or *foreign* language skills is not well known. The mere fact that such differentials emerge implies that they contribute to the productivity of labor; despite recent advances, the precise processes at hand, however, remain little understood.

This value-creation process can be analyzed in terms of language use as opposed to mere competence. One reason why economists working on language have so far referred to competence rather than use in empirical work is that the structural relationships between competence and use are still not very well known. Another reason for economists' focus on competence is the lack of hard data on language use, particularly of data sets that could serve to connect language use to earnings. However, there is evidence for Quebec that an increase in the share of Francophone ownership of a sector increases the use of French at work in that sector, and an increase in the importance of external markets for a sector reduces the use of French at work in that sector. Additional evidence for Quebec shows that ownership, and thus (because the former co-determines the latter) language used at work, matters to economic outcomes at the firm level. Anglophone Canadian and foreign-owned (American, and thus Anglophone in practice) manufacturing establishments operating in Quebec are more productive and more export-oriented than Francophone-owned establishments (Raynauld & Vaillancourt, 1984).

One set of results for Switzerland shows that a mainly international orientation, for a business, has a strong positive effect (in both language regions) on the likelihood of its employees using English. Another shows that the use of English at work increases when sales or purchases in that language represent a higher share of sales or purchases overall (Grin, Sfreddo, & Vaillancourt, 2010).

Future Avenues and Related Topics

The study of multilingualism in economic activity covers only a part of the economics of language and multilingualism, which also includes the reciprocal influence of economic variables on linguistic ones, thus contributing to the understanding of language dynamics and the selection, design, and evaluation of language policy and planning (LPP).

However, even within the confines of the issue of multilingualism in economic activity, many questions remain open. While it is obvious, for example, that a broader range of language skills facilitates access to foreign suppliers, as well as to clients who prefer to speak a language different from that of the producer, it remains difficult to move beyond case-specific observations and to generalize about the importance of multilingualism in economic activity.

One relatively under-researched topic is the economic weight of intrinsically language-related activities, particularly in publishing and translation, largely because it is not evident that this raises questions analytically different from those that arise in the context of *any* productive activity. However, these sectors could be included in broader approaches that attempt to do justice to the importance of language across all economic activities. At the time of writing, two avenues appear to be particularly promising.

First, recent work by Spanish economists (Martín Municio, 2003; García Delgado, Alonso, & Jiménez, 2007) proposes to identify the linguistic intensity embedded in products in order to estimate linguistic intensity coefficients by groups of products or economic sectors, thereby adding a fascinating linguistic dimension to national macroeconomic accounts. This approach, whose initial aim was to assess the relative weight of "communication" (even in a first language) to value added at each successive stage of a production process, could be adapted to assess the role of second or foreign languages.

Second, the question arises of whether multilingualism is economically profitable only because it allows for more cost-effective purchasing or more robust sales *in a multilingual world*, or because it is a good thing *in the absolute*—the implication being that the loss of linguistic diversity would be intrinsically costly from an economic standpoint. In order to assess this point, it is necessary to check if multilingualism, whether in individuals or

organizations, contributes to value creation, for example by making individuals more creative, or teams more responsive to market needs. This could be linked up to investigations in both management research about the performance of teams in multilingual settings (Marschan-Piekkari, Welch, & Welch, 1999) and functional pragmatics (Behr, Hentschel, Kauffmann, & Hern, 2007). Further linkups with the economics of information and communication (Crémer, Garicano, & Prat, 2007) could also be envisaged. At this time, there is no conclusive research on such effects, but recently collected circumstantial evidence suggests that linguistic diversity does generate positive effects of this kind, making a multilingual world more prosperous than one operating through the medium of one language only (Simonton, 2008).

To sum up, the study of the role multilingualism in economic activity has already delivered an important array of results confirming that the use of skills in several languages has major economic implications, but many aspects of the underlying links have, at this time, only been glimpsed at and deserve further research.

Multiliteracies in Education

MARY KALANTZIS AND BILL COPE

Definition

The term *multiliteracies* refers to two major aspects of communication and representation today. The first is the variability of conventions of meaning in different cultural, social or domain-specific situations. These differences are becoming ever more significant to the ways in which people interact in a variety of social contexts. As a consequence, it is no longer sufficient for literacy teaching to focus, as it did in the past, primarily on the formal rules and literary canon of a single, standard form of the national language. Rather, the sociolinguistic conditions of our everyday lives increasingly require that we develop a capacity to move between one social setting and another where the conventions of communication may be very different. Such differences are the consequence of any number of factors, including, for instance, culture, gender, life experience, subject matter, discipline domain, area of employment, or specialist expertise. For this reason, a multiliteracies approach to literacy suggests we needed to move toward a discipline grounding for literacy learning that takes its cue from contrastive linguistics. Such an approach is based in an account of discursive differences and how one learns to move between different representational settings.

The second aspect of language use highlighted by the idea of multiliteracies is multimodality. Multimodality arises as a significant issue today in part as a result of the characteristics of the new information and communications media. The asynchronous meanings across distance that were once the main preserve of the written word are now made in conditions where written linguistic modes of meaning interface with recordings and transmissions of oral, visual, audio, gestural, tactile, and spatial patterns of meaning. For these reasons, the multiliteracies case is that we need to extend the range of literacy pedagogy so that it does not exclusively privilege alphabetical representations. In today's learning environments, we need to supplement traditional reading and writing with these multimodal representations, and particularly those typical of the new, digital media.

Background

The term "multiliteracies" was coined in 1994 by the New London Group, a group of scholars who came together to consider the current state and possible future of literacy pedagogy. The group consisted of Courtney Cazden, Bill Cope, Norman Fairclough, Jim Gee, Mary Kalantzis, Gunther Kress, Allan Luke, Carmen Luke, Sarah Michaels, and Martin Nakata. The group's initial deliberations produced an article-long manifesto (New London Group, 1996) and then an edited book (Cope & Kalantzis, 2000) which includes the original article. In 2009, in consultation with other members of the group, Cope and Kalantzis published a paper reflecting on subsequent developments (Cope & Kalantzis, 2009).

Sociolinguistic Context

The “pedagogy of multiliteracies” as presented in these key texts, took the form of a programmatic manifesto, grounded in a reading of the changing sociolinguistic context. The world was changing in dramatic ways, these interventions argued, and with it our communications environment. For some quite fundamental reasons, literacy teaching and learning would have to change too. The analysis presented by the New London Group was based in an interpretation of changes in the worlds of work, citizenship, and personal life.

In terms of the first of the two dimensions of multiplicity, we were and still are witnessing a burgeoning variety of what Gee calls “social languages” in national, ethnic, subcultural, workplace, interest, or affinity group contexts (Gee, 1996). For all the signs that English is becoming a world language, it is also diverging into multiple Englishes at the levels of dialect and register. Whereas traditional literacy curriculum was taught to a singular standard (grammar, the literary canon, standard national forms of the language), the everyday experience of meaning making is increasingly one of negotiating discourse differences.

In terms of the second of these two dimensions, the new, digital media accelerates a trend away from a world which privileged the written word as the preeminent site of cultural and epistemic power, to one in which the visual and other modes are becoming considerably more important (Kress, 2009). We have also seen the rise of new and pervasive forms of writing which are in some respects more like speaking than traditional writing: emails, synchronous instant messaging, asynchronous text messaging, and social media posts. These are just a few of the changes which have pervasively changed the communicative spaces of work, public life, and personal identity formation. They are practical reasons that suggest the importance of moving in the direction of a multimodal conception of “literacies” in the plural (Jewitt, 2008). As a consequence, the multiliteracies case is that we need to extend the range of literacy pedagogies so that they do not excessively privilege alphabetical representations, supplementing them in the classroom with multimodal representations, and particularly those typical of the new, digital media.

Design and Multimodality

In a pedagogy of multiliteracies, all forms of representation, including language, are regarded as dynamic processes of transformation rather than processes of reproduction. That is, meaning makers are not simply replicators of representational conventions. Their meaning-making resources are to be found in available representational artefacts (written texts, images, multimodal texts, etc.), patterned in familiar, conventional, and thus recognizable ways. However, meaning makers always rework these objects. They do not simply use what they have been given: they are fully remakers of signs and transformers of meaning. The meanings they make are never quite the same as the resources for meaning from which they draw.

The pedagogical implications of this shift in the underlying conception of meaning making or semiosis are significant. In the old literacy, learners were passive recipients of systems of representation, expected to reproduce received, sanctioned, and authoritative forms of language. The logic of literacy pedagogy made it an instrument of social design which buttressed a regime of apparent stability and uniformity (Kress, 2003).

A pedagogy of multiliteracies, in contrast, requires that the enormous role of agency in the meaning-making process be recognized. Through this recognition, it seeks to create a more productive, relevant, innovative, creative, and even life-transforming pedagogy. Literacy teaching is not about skills and competence: it is aimed at creating a kind of

person who is an active designer of meaning, with a sensibility open to differences, change, and innovation. The logic of multiliteracies recognizes that meaning making is an active, transformative process, and a pedagogy based on that recognition is more likely to open up viable life courses for a world of change and diversity.

The multiliteracies theory replaces static conceptions of representation such as “grammar” and “the literary canon” with a dynamic conception of representation as “design.” The word “design” has a fortuitous double meaning, simultaneously describing intrinsic structure or morphology, and the act of construction. Design in the sense of construction, is something that you do in the process of representing meanings, to oneself in sense-making processes such as reading, listening or viewing, or to the world in communicative processes such as writing, speaking, or making pictures. The multiliteracies view of design has three aspects: (*available*) *designs* (found representational forms); the *designing* one does (the work you do when you make meaning, how you appropriate and revoice and transform available designs); and the (*re-*)*designed* (how, through the act of designing, the world and the person making meanings are transformed). No two acts of design simply reproduce the world as found. They re-represent the word, adding inflections of identity and voice, sometimes subtly, other times significantly, but always importantly.

In its more recent iterations, multiliteracies theory suggests there are seven modes of meaning: written, oral, audio, visual, spatial, tactile, and gestural modes (Kalantzis & Cope, in press). Written meaning is significantly different in its characteristic forms from oral meaning, even though it is closely linked through language. There are also in today’s new media some increasingly important, hybrid forms. Written and visual meanings are closely juxtaposed in today’s communications environment. Meanwhile, oral and audio modes are closely related, not only in everyday speech, but in audio and visual recordings. Written meanings are framed by place and tangible objects (spatial and tactile meanings). Gestural meanings are not only integral to speech: they are also communicated synchronously and asynchronously in video. Most things that can be expressed in one mode can be expressed in another, to the extent even that linguistic meanings in their entirety can be carried in writing, speech, touch (Braille), and gesture (sign languages).

In a pedagogy of multiliteracies, the grammar of writing is replaced by a more broad-ranging “design analysis,” in which capacities to mean the same kinds of thing can be found across all modes. However, each mode also offers characteristic affordances. We can picture a scene visually in a painting or a photograph for someone who is not present. We can also describe the same scene in writing. These are both modes of representation at a distance. However the semantic effects can never be the same. And the mode of interpretation of the represented meaning by the viewer or reader is always and essentially different. In Kress’s explanation, image favors simultaneity (seeing the picture all at once); writing favors temporal and causal sequences (working one’s way consecutively across interlinked clauses) (Kress, 2003).

Not only are more of our contemporary texts multimodal, in which modes are inextricably juxtaposed, but multiliteracies theory also suggests that our human meaning capacities are always intrinsically synaesthetic. We naturally and continuously move between one mode and another. The metaphors which drive our meaning systems confirm this contention. Consider, for instance, the pervasiveness in our oral and written language of words for seeing, feeling, and being in space.

Traditional schooling artificially attempts to isolate the meaning system of language, privileging in particular conventional alphabetical literacy. Doing this is to neglect the power of mode shifting as a learning strategy, representing a learnable meaning in one mode then another, or in parallel in two or more modes.

A considerable amount of work has been done in recent years to analyze the use of multimodal texts in everyday life and classrooms. Kress and colleagues have conducted

seminal theoretical and empirical work, “parsing” everyday multimodal and classroom texts (Kress & van Leeuwen, 1996; Kress, 1999; Kress, Jewitt, Ogborn, & Tsatsarelis, 2001). Unsworth has undertaken comprehensive analyses of a range of multimodal classroom texts (Unsworth, 2001; Unsworth, 2009). Many other outstanding analyses have been made of the uses of multimodal texts in the classroom (Stein, 2001; Chandler-Olcott & Mahar, 2003; Hull & Nelson, 2005).

Pedagogy

In the original formulations of the New London Group, four major dimensions of pedagogy were identified: *situated practice*, *overt instruction*, *critical framing*, and *transformed practice*. In applying these ideas to curriculum practices over the past decade, Kalantzis and Cope have reframed these ideas somewhat and translated them into the more immediately recognizable “knowledge processes”: *experiencing*, *conceptualizing*, *analyzing*, and *applying* (Kalantzis & Cope, 2010).

Whichever terminology is used to categorize learning activity types, the essential idea in the multiliteracies approach is that learning is a process of “weaving” backwards and forwards across and between different pedagogical moves (Luke, Cazden, Lin, & Freebody, 2004):

Situated practice/experiencing: Human cognition is situated. It is contextual. Meanings are grounded in real-world patterns of experience, action and subjective interest (Gee, 2004).

One key pedagogical weaving is between school learning and the practical out-of-school experiences of learners. Another is between familiar and unfamiliar texts and experiences. These kinds of cross-connections between school and the rest of life Cazden calls “cultural weavings” (Cazden, 2006).

Overt instruction/conceptualizing: Specialized, disciplinary knowledges are based on finely tuned distinctions of concept and theory, typical of those developed by expert communities of practice. Conceptualizing is not merely a matter of teacherly or textbook telling based on legacy academic disciplines, but a knowledge process in which the learners become active conceptualizers, making the tacit explicit and generalizing from the particular. In the case of multiliteracies teaching and learning, overt instruction/conceptualizing involves the development of a metalanguage to describe “Design Elements.”

Critical framing/analyzing: Powerful learning also entails a certain kind of critical capacity. “Critical” can mean two things in a pedagogical context—to analyze functions or to be evaluative with respect to relationships of power (Cazden, 2006). In the case of a pedagogy of multiliteracies, this involves analyzing text functions and critically interrogating the interests of participants in the communication process.

Transformed practice/applying: This entails the application of knowledge and understandings to the complex diversity of real-world situations. In the case of multiliteracies, this means making texts and putting them to use in communicative action.

These dimensions are pedagogical orientations or knowledge processes. They are not a pedagogy in the singular or a sequence to be followed. Rather, they are a map of the range of pedagogical moves from which to choose. They also have their roots in well-known pedagogical traditions, extending these traditions by supplementing them in order to offer students a more balanced range of activity types. Didactic teaching tends to emphasize the overt instruction of conceptual, disciplinary schemas at the expense of experiential and critical activities. Progressivisms tend to focus on grounded learner experiences, sometimes

neglecting deep conceptual work. Critical pedagogy adds analysis and application to the mix, but sometimes leaving little time for harder edge conceptual learning processes and for moving students into new and unfamiliar experiential domains. Multiliteracies pedagogy connects with all major pedagogical strategies, suggesting however that teachers supplement their existing practices by expanding the range of their pedagogical repertoires.

In contemporary classrooms where extraordinary diversity is typically highly visible, the capacity of a pedagogy of multiliteracies to address learner differences has now been well documented (Healy, 2007; Cummins, 2009). The multiliteracies approach suggests alternative starting points for learning in the varied experiential worlds of learners. It allows for alternative forms of engagement, or divergent learning orientations in the form of a variety of knowledge processes. It allows for different modalities in meaning making, embracing alternative expressive potentials for different learners and promoting synaesthesia as a learning strategy. It also recognizes the active nature of “design” and the learning potentials that arise from expressing identity in the learning process (Kalantzis & Cope, 2008; Mills, 2010).

There is now substantial literature documenting multiliteracies pedagogies in practice (Anstey & Bull, 2006; Cole & Pullen, 2009). Kalantzis and Cope have adapted and extended the original multiliteracies pedagogy in their “learning by design” approach and Web-learning design and delivery platform, which a number of researchers have tested and reported upon (Mills, 2006; Neville, 2008; Cloonan, 2010; Cloonan, Kalantzis, & Cope, 2010; Pandian & Balraj, 2010; van Haren, 2010). An exciting body of work has also emerged from South Africa, centered around the research of Denise Newfield and Pippa Stein (Newfield et al., 2001; Stein & Newfield, 2002).

Multimodal Communication: Overview

SIGRID NORRIS

Introduction

There is an increasing interest among academics, professionals and students in the role of image, gesture, gaze and posture, and the use of space in representation and communication—in other words, multimodality. (Jewitt, 2009, p. 1)

The study of multimodal communication is relatively young as it developed with the development of digital media technologies from video recorders to computers. The developing area of study is vast and cuts across many fields from MULTIMODAL DISCOURSE ANALYSIS and MULTIMODAL TEACHING AND LEARNING to MULTIMODAL LITERACY, MULTIMODAL TEXT ANALYSIS, and MULTIMODALITY AND SYSTEMIC FUNCTIONAL ANALYSIS.

Multimodal communication looks at language within and as part of a larger whole. When investigating an interaction for example, multimodal researchers investigate not only the language that is spoken, but also the gestures that are performed by the speakers and the proxemics that the speakers take up to one another (Norris, 2004, 2011). When investigating a text, multimodal researchers not only investigate the written language, but also the images that are present on a page and the layout of the text itself (Kress & van Leeuwen, 1996; Djonov & van Leeuwen, 2011; Al Zidjaly, 2011).

By looking at communication in its vast complexity, multimodal communication researchers investigate how the multimodal complexity is produced, how it is perceived, or both. Essentially, all areas of applied linguistics can be studied through a multimodal lens.

What Are the Primary Directions of Multimodal Methods?

Multimodal research methods primarily come from three more or less distinct directions: (a) systemic functional linguistics (O'HALLORAN, KAY L.), (b) social semiotics (KRESS, GUNTHER and VAN LEEUWEN, THEO), and (c) mediated discourse analysis (SCOLLON, RON, JONES RODNEY H., and NORRIS, SIGRID). While the areas of inquiry are somewhat distinct, there are also overlaps among them; and there are greater overlaps between systemic functional linguistics and social semiotics, and between social semiotics and mediated discourse analysis.

What Is Investigated in Multimodal Communication?

Multimodal communication researchers, like all applied linguists, are highly interested in the role that language plays in social life; however, rather than paying exclusive attention to language, multimodal communication researchers pay as much attention to other modes such as images or gestures, gaze, or posture. Digital media development suddenly allowed for easy (and inexpensive) video recording, the possibility of TRANSCRIBING MULTIMODAL INTERACTION and with it the analysis of interactions, leading to studies in MULTIMODALITY

2 MULTIMODAL COMMUNICATION: OVERVIEW

AND IDENTITY CONSTRUCTION, MULTIMODALITY IN WORKPLACES, and MULTIMODALITY AND RITUAL.

Just as researchers became interested in the multimodality of interaction, they investigated more ephemeral concepts such as MULTIMODALITY AND TIME or tried to examine MULTIMODALITY AND RHYTHM, but they also paid closer attention to MULTIMODALITY AND THE SENSES and broached broader questions of culture and globalization and social causes as can be found in MULTIMODALITY AND CULTURE, MULTIMODALITY AND GLOBALIZATION, and MULTIMODALITY AND DISABILITY.

Most clearly and explicitly, we find a link to developing technologies in areas such as MULTIMODALITY AND TECHNOLOGY, MULTIMODALITY AND SOFTWARE, and MULTIMODALITY AND HYPERMEDIA. However, while the area of multimodal communication did develop because of developments in digital media, researchers are also interested in other forms of media from a multimodal perspective. Some of these are MULTIMODAL TEXT and MULTIMODALITY AND COMIC BOOKS, or MULTIMODALITY AND DISPLAYED ART and MULTIMODALITY AND FILM, MULTIMODALITY AND METAPHORS, and MULTIMODALITY IN CORPORATE COMMUNICATION.

Multimodal Computer-Mediated Communication and Distance Language Learning

REGINE HAMPEL

With the development of digital technologies over the past decades, distance language learning has changed dramatically. While earlier courses depended on tailor-made printed materials and used one-way communication tools to foster students' acquisition of listening skills and to a limited extent their speaking skills, new multimodal tools allow for interaction via text, audio, graphics, and video. In line with this, the pedagogical focus has shifted from learner independence to interaction between students to promote learning. In this way, distance language learning is also becoming a less specialized field, with campus-based institutions introducing courses that include distance learning, and distance institutions relying more on interaction and less on custom-made materials.

At the beginning, distance *language* learning was informed by the traditional approach of distance education, which took the form of correspondence courses. In this model learners were dispersed and isolated from their institution, their teacher, and their peers. To ensure that students were able to cope with the subject in question, the Open University in the UK developed its own approach to distance learning in the 1960s when course writers decided not to rely on existing textbooks but to produce their own tailor-made materials—an approach that has been taken up by other distance education institutions around the world. Thus courses were designed as “tutorials-in-print” (Rowntree, *n.d.*), containing the voice of the teacher and helping learners to study on their own and develop independent study skills in terms of navigation of materials, self-motivation, and self-reflection. In addition, learners tended to be supported through regular written feedback by a teacher. Research that accompanied this “first generation” approach (Wang & Sun, 2001) focused on learner independence, autonomy, and motivation (Hurd, Beaven, & Ortega, 2001).

If one perceives learning as social practice, the main limitation of this approach consists in the lack of interaction with others. Learning that is characterized by limited scaffolding by the teacher, lack of feedback from peers, and little joint construction of knowledge not only has an impact in terms of cognitive development but also has social and affective implications, captured in the expression “the loneliness of the distance learner.” In distance language education, where oral and aural skills are crucial, these shortcomings are exacerbated. As a result, technology started to be used in the second and third generations of distance courses, and audiovisual resources were introduced to complement the traditional print media in the form of films, cassettes, CDs, TV, followed by CD-ROMs, DVDs, and Web-based CALL material. However, while these one-way communication media have the potential to develop learners' aural skills and some oral skills (e.g., pronunciation), they do not contribute to fostering interactive oral skills. Telephone tutorials were a first step toward giving learners access to synchronous two-way communication in distance language learning.

2 MULTIMODAL COMPUTER-MEDIATED COMMUNICATION

With this, a model of distance education was achieved that is characterized by the following features (Garrison & Shale, 1987, p. 11) and that still holds today.

- Distance education implies that the majority of educational communication between (among) teacher and student(s) occurs non-contiguously.
- Distance education must involve two-way communication between (among) teacher and student(s) for the purpose of facilitating and supporting the educational process.
- Distance education uses technology to mediate the necessary two-way communication.

More recently, the development of new technologies in the form of computer-mediated communication (CMC) has had a major impact on distance language learning, thus creating a fourth generation of courses. Here the idea of learner independence has been replaced with one of “collaborative control, based on a belief that learners can best achieve autonomy and control within their learning experiences when they can collaborate with others in ways which support their learning. It places emphasis on the exchange of ideas and the development of abilities within collaborative learning experiences” (White, 2004, p. 4).

Initially, CMC was limited to asynchronous written tools such as forums, which allowed for writing and spatial organization of messages. Synchronous written chat followed, and the 21st century has seen the advent of an array of multimodal environments, including audio and video conferencing, virtual worlds, and social networking tools. Educational institutions increasingly make use of complex virtual learning environments (VLEs such as Moodle or Blackboard, also known in American contexts as learning management systems [LMSs] or content management systems [CMSs]) which deliver content as well as integrate a range of communication tools. Besides using such purpose-built tools, educators are also turning to publicly available environments such as Second Life. With online tools providing language teachers and learners access to two-way communication that is independent of place and—in the case of asynchronous environments—time, interaction at a distance between learners has become easier, both in written and in spoken formats. In the distance language education context, access to online tools that allow for spoken interaction is particularly crucial, thus “addressing, at least to some degree, the lack of in situ speaking practice, one of the apparent shortcomings of learning language at a distance” (Blake & Delforge, 2006, p. 129). As a result, the number of institutions teaching languages at a distance has increased (Blake, 2007).

At the same time, interaction itself as well as the understanding of interaction has become more complex: In these new digital environments meaning is made multimodally and communication is seen as mediated. As Kress and van Leeuwen (2001, p. 20) explain, multimodality is “the use of several semiotic modes in the design of a semiotic product or event, together with the particular way in which these modes are combined—they may for instance reinforce each other . . . , fulfil complementary roles . . . or be hierarchically ordered.” In online environments, the written linguistic mode (in the form of text) can be combined with the spoken linguistic mode (audio) as well as spatial-visual (architecture and other structural functions) and gestural modes (body movement) to “orchestrate meaning” (Kress, Jewitt, Ogborn, & Tsatsarelis, 2001, p. 25). In one way, the new environments where users can see and speak with others, work jointly on texts, or collate information thus seem to replicate more traditional communication in a face-to-face classroom. However, the mediational means, which in the case of CMC consist of the computer and the tools used, together with their modes and affordances, shape the action in essential ways (Wertsch, 1991, p. 12). When using a video-conferencing environment, for example, rather than a face-to-face meeting to hold a discussion, the following factors have an effect on how meaning is made via the video conference and how social relationships are negotiated:

- availability of tools, such as text chat, whiteboard, application sharing, Web tour;
- availability of modes, such as linguistic written, linguistic spoken, gestural, spatial;
- functionalities of the application, such as presentation of webcam image, system for turn taking, levels of permissions, recording facility; and
- technical matters, such as transmission rate.

Such technological developments and their increased implementation in language learning are posing new challenges for distance teachers and institutions, and the focus of interest in pedagogy and research has shifted to issues that are related to concepts such as interaction, collaboration, participation, social presence, community, and learner networks (White, 2004, p. 4). This includes research in the following areas:

- learner- and teacher-related aspects, including interaction and negotiation of meaning, collaboration, community building, identity, power relations, learning strategies, motivation, group autonomy, role of the teacher, task design, and assessment;
- more general aspects of online communication and language learning, such as intercultural learning, multiliteracies, online discourse, mediation and affordances, or access to digital resources;
- methods of online learning and teaching, such as telecollaboration, tandem learning, task-based language learning, and collaborative learning; and
- use of specific online tools, such as mobile devices, virtual worlds, blogs, and wikis.

Many institutions now follow a blended model of language education by combining traditional modes of delivery (e.g., printed books and DVDs with audio and visual materials) and e-learning (e.g., through the use of a VLE or of a mix of individual tools). In this way, written course materials and student-computer-based activities can be used to deliver content to individual learners; to teach reading, writing, and listening skills; to give students the chance to rehearse speaking skills (e.g., through recordings); and to promote focus on form and improving accuracy.

On the other hand, online activities offer the opportunity for interaction with other people, with multimodal CMC tools increasing the range of activities available to learners and teachers engaged in distance education and widening the objectives that can be attained. These include cognitive benefits in terms of second language acquisition, as well as socio-affective benefits. Activities include spoken and written discussions between learners or between learners and their teacher, which can foster fluency (in the case of synchronous communication) or accuracy (when using asynchronous tools such as forums or sharing audio files). Wiki activities can promote joint knowledge building, and personal blogs can be used to foster social interaction. Tandem-style tasks with students of other languages give learners the opportunity to meet native speakers and encourage intercultural learning, and activities in virtual worlds or online games can promote communication with “real” users of the technology. In this way, online interaction can create a sense of community for the erstwhile lonely distance learner: Blake (2005) calls synchronous CMC the “glue” between students engaged in distance learning. Last but not least, by making written records of use available, CMC also offers the possibility of focusing on the process of learning rather than just the product—thus fitting in with current theories of learning—and allowing learners to reflect on their learning.

However, this new approach to distance learning through the use of CMC also poses a number of challenges. Not all learners possess the new literacy skills that are necessary for learning a language at a distance today, and they may be cognitively overloaded when required to engage with a new language, unfamiliar content, unknown peers, and novel technologies (Lankshear & Knobel, 2003). Motivation can cause problems too; some distance

students do not see the value of CMC activities—in particular those activities that involve peers rather than the teacher—and prefer more traditional tasks. Also, clashes in cultures-of-use have been observed (Thorne, 2003), with students' use of technologies for social purposes conflicting, for example, with what they are expected to do in an educational setting. And linking students with native speakers in tandem set-ups or through virtual worlds can cause friction or lead to failed communication (O'Dowd, 2006).

Teaching online and at a distance requires particular skills (Hampel & Stickler, 2005). Not only do teachers and course developers have to be familiar with the technology but they also have to be aware of the implications that the use of CMC has in the context of language teaching. They have to find a balance between learner support and learner autonomy while also developing group autonomy (Mangenot & Nissen, 2006). They have to ensure that the task design is appropriate to the tool (Hampel, 2006). Assessment of online activities is another issue as assessing the process of learning is more complex than focusing on the product, and institutions are often not willing to engage in assessing collaborative work (Lamy & Hampel, 2007).

Finally, at institutional level, there is the need for an informed choice of tools. Institutions can select between tailor-made technology, off-the-shelf tools for specific (educational) purposes, open-source educational tools (e.g., Moodle), and publicly available social networking tools. Crucially, this choice has to be informed by appropriate pedagogies that focus on promoting interaction as well as supporting learners. In addition, teachers have to be supported to develop the requisite skills for teaching online and at a distance. As White (2006, p. 261) points out, "providing high-quality distance language learning opportunities for all learners is still a key challenge for the field."

Multimodal Corpus-Based Approaches

JOHN A. BATEMAN

Nowadays there is a considerable awareness of the necessity of studying language and language use *in association with* accompanying modes of communication. For example, whereas in the early 2000s one might have found studies of “the language of advertising” focusing solely on the linguistic component, corresponding studies now also consider visual contributions and attempt to describe and explain the interplay of the verbal and the visual in an integrated meaning-making artifact. This broadening of the targeted scope of analysis is echoed across the board in applied studies and has given rise to the consideration of multimodal corpora.

Corpus-based approaches in linguistics in general are based on appropriately *selected* and appropriately *prepared* data in sufficient *quantity* to allow empirical, data-driven research. These areas have been investigated substantially for text-based data and there are powerful tools and mechanisms available for supporting investigation. The key to using corpora for research lies, however, in the “prepreparation” of their data. To support the search for patterns, relevant properties of the data must be rendered machine-accessible so that large-scale searches and collations of results may follow. For traditional written-text data, simply having the text in electronic form already allows useful access. Patterns can be sought by using straightforward string searches and statistical overviews, key-word-in-context lists, concordances, frequency data, n-grams, and many more.

The greater the extent of “enrichment” of the basic text data available, the more valuable the corpus becomes. Most corpora nowadays consequently include part-of-speech tagging, so that it is possible to ensure that the desired form of otherwise ambiguous words is found (e.g., *works* as noun rather than as verb). Corpora also commonly include basic text-type and contextual information, so that it becomes possible to see if there are statistically reliable differences between, for example, narrative and scientific texts, or between learner and non-learner data, or across gender and so on.

An increasing number of corpora include information going beyond part-of-speech tags and allow access to more or less complex syntactic and semantic categories and structures. Such corpora are of considerable utility, supporting applications ranging from basic linguistic research, to finding balanced and natural teaching materials for language teaching, to providing seed data for sophisticated machine-learning algorithms for inducing linguistically relevant information, and much more. Given the success of such methods, it is natural that an extension beyond written-text data be considered. This is the direction of development broadly categorized as *multimodal* corpus analysis because the data at issue involve information beyond or alongside any written language deployed. Written text is then seen as a particular “mode” of linguistic presentation and information beyond this brings in other modes.

Multimodal corpus approaches will certainly play just as important a role in research as text-based corpora already enjoy. But there are nevertheless some basic problems to be solved. Some areas included within the broader category of multimodal corpora are considerably more developed than others—the clearest example is offered by speech corpora, that is, corpora that include in addition to their representation of the words said information about intonation, timing, hesitation, and so on; most other areas can still only be considered experimental.

This entry accordingly characterizes the distinct kinds of multimodal corpora currently envisaged and describes to what extent the prerequisites of selection, preparation, and quantity are met. Different kinds of data raise different kinds of problems. This is important both for designing tools and for considering combinations of types of data—always a central concern when considering *multimodal* data. Explorations in developing multimodal corpus work often fail to leverage appropriately off already existing techniques. In future, this will need to be addressed more effectively since the natural complexity of multimodal data can easily overwhelm individual efforts.

The broadest distinction is between *linear* and *nonlinear* data. This is an essential distinction since many discussions of “multimodal” corpora are situated entirely within one area (typically the first) rather than the other. Many discussions of multimodal corpora and tools accordingly *only* consider linear data and provide no support for, or even mention of, nonlinear data.

Linear data include material which is essentially organized to unfold along a single dimension of actualization. This dimension may either be in space, as in traditional written-text data, or in time, as in recordings of spoken language. In both cases the single dimension of organization allows relatively straightforward access to any part of the data: In the case of written data we have the explicit ordering information about the words and characters represented—for example, word number 13,219 of *War and Peace*—while in the case of spoken language data, we have the time at which some phonetic event occurs. For this reason, speech corpora generally work with *time-stamped* data. This continues to apply when that further information is itself complex, as in video data; even here, the basic temporal organization remains of considerable benefit when designing corpora and corpus tools.

Nonlinear data include material where there is no single organizing dimension that can be used for providing access. This generally involves spatially *distributed* information, such as that found on pages of documents, printed advertisements, paintings, and so on. As we shall see, corpora for this area are in a far less developed state. Tools built for linear data are generally unusable for nonlinear data, although some developments are being attempted.

Further dimensions that we will combine with the above are usually seen in terms of *sensory channels*. For example, the data may be essentially graphically visual, as in video data or paintings, or acoustic, as in speech corpora, or linguistically visual, as in typography and text layout. The sensory channel view alone is insufficient for effective corpus design, however, since each sensory channel can in fact carry very different kinds of information that need to be distinguished when preparing data for inclusion in corpora. Moreover, a strong interdependence exists between the kinds of corpora that are attempted and the technological support available for storing and manipulating the required data. There is also the question of just what kinds of data are considered as sensible targets for investigation at all. Both areas have changed considerably in recent years.

Linear Data

In this section we briefly run through some of the types of data and corresponding corpora that can be considered to be organized as a one-dimensional unfolding of information. We will see that that information can then itself come to include substantial multimodal contributions that are no longer one-dimensional; nevertheless their embedding within a single dimension of unfolding provides a critical foundation for applying corpus methods effectively.

The Emergence of Multimodal Corpora: Spoken Language Corpora

The entire field of multimodal corpora began with the rather obvious wish to include not only textual “transcriptions” of spoken language but the spoken language itself, that is, the raw recorded speech events themselves. From the perspective of empirical research, this was clearly a useful goal: Just as the collection of corpora of written data had opened up access to language as it is actually used in written texts, so the provision of spoken language corpora was similarly seen as allowing more empirically well-founded studies of intonation, speech quality, corrections and hesitations, and so on. Such speech data are now also commonly employed for purposes such as training speech recognition systems to improve robustness in the face of real-life variation. The move, from the generally assumed *monomodality* of instances of written language to the evident *multimodality* of spoken language data, marked the beginning of the field of multimodal corpus construction.

Just as text corpora could draw on the long history of linguistic description for morphology, grammar, semantics, and so on for designing *linguistic annotations* of the data stored, spoken language corpora could similarly include theories of intonational phrasing and phonetics as motivations for additional information, easing access to the data stored. Even more than is the case for text descriptions, however, the “mixing” of information of fundamentally distinct kinds—digitized acoustic data and textual transcriptions and annotations—demanded a strongly *layered* approach to corpus construction. This is the issue of how best to facilitate access to data once collected. It is not sensible, for example, to put such additional information directly into the middle of sound data. The usual approach is then to employ *standoff annotation* (Thompson & McKelvie, 1997), whereby annotations are stored separately and provide “indexes” into the stored sound data.

Layers, often called *tiers* in work on multimodal corpus tools, provide a powerful mechanism for maintaining the results of different kinds of processing and linking these together with respect to the source data: For example, the original speech data might be kept in a single “layer” and a transcript of that data in another. The transcript might in turn be subject to lexical stemming or grammatical analyses and the results of these processes (necessarily automatic when large amounts of data are considered) may be added into further layers. The speech data themselves might then also be processed in various ways—for example, to produce analyses of fundamental frequency, formants, or a segmental phonetic description—and each of these can be included in distinct additional annotation layers. The combined result of such processing is then a complex, interlinked set of information that provides multiple perspectives on the data in order to support a considerable range of linguistic investigation.

As effective corpus work requires that sufficient *quantity* of data be available, it is also important to consider the kinds of tools that may be applied in order to turn “raw data,” such as sound recordings, into accessible, appropriate, preprepared data amenable to automatic searches and pattern matching. For speech corpora, clearly the most important advance that has made this possible is the broad availability of speech processing software. It is now straightforward to turn large quantities of recorded speech data into time-dependent tracks of data relevant for linguistic research. This is dealt with at length elsewhere; important here, however, is the support that layering provides for the *combination* of modalities as we go further into multimodality.

Annotations and Markup Languages

Being able to store large quantities of such data is necessarily accompanied by the problem of accessing that data in ways useful for conducting research: Even searching for text within text files, although relatively simple, is not itself optimal for linguistic research. Typically one is searching for more abstract patterns than are present in the bare text. As noted

above, textual corpora are accordingly “annotated” with additional information, such as part-of-speech information, grammatical categories, semantic labeling, and so forth, that increases their value for linguistic research. When other kinds of data are considered—for example, searching speech data for acoustic events—the problem grows considerably. There are many open questions concerning the kinds of annotations and processing techniques that will make multimodal corpora most useful. In short, the further we move away from corpora consisting of plain written text, the more difficulties and open questions we are confronted with.

Most corpora nowadays draw on a particular technology for storing and organizing their data in a form that makes them both accessible and capable of being arbitrarily enriched with further annotations: This technology is that provided by *Extensible Markup Language* (XML). XML provides a straightforward, machine-readable format that allows information to be annotated, or marked up, as desired; it is an outgrowth of a long history of research on document markup and is the current recommendation for structured data of the World-Wide Consortium W3C (<http://www.w3.org/TR/xml>).

An example of a simple XML markup for part of speech is the following, slightly amended from the British National Corpus (www.natcorp.ox.ac.uk):

```
<w id="w345" c5="CJC" hw="but" pos="CONJ">But</w>
```

Here we can see that an XML expression consists of some data enclosed by a labeled opening tag and a matching labeled closing tag: in this case `<w . . >`, indicating a word, and `</w>` respectively. The raw data are what is between these opening and closing tags: in this case the characters “but.” Central to the utility of the framework is the fact that each opening tag can contain predefined attributes and values, giving further information about the tagged item. In the present case, the opening tag specifies that the tagged material belongs to the particular word class “CJC,” has the “headword” “but,” and the part-of-speech information “CONJ,” and has been given the (unique to the current document) identifier “w345.” In addition, tags can be nested hierarchically, making it possible to construct arbitrarily complex (but well-formed) structures.

This is an example of “in-line” markup, where the information about the data is contained in the same file as the data themselves—the occurrence of the word “but” in some text, in the present case. In contrast to this, standoff annotation as introduced above works by putting the information about the data in a separate file and referring to the original data with a *cross-reference* to some identifying feature of the data. That identifying feature can either be something like the explicit identifier given in the example with the “id” attribute or draw instead on some logical property of the file, such as the *n*th character in the file. The advantages of such standoff annotation are that structures can be defined that do not need to nest properly, which is useful in many cases of linguistic information because the levels of abstraction are orthogonal and do not necessarily nest one within the other (e.g., syntactic structure, intonational phrasing, and typography), and arbitrary kinds of information can be added in a modular and still processible fashion. This becomes increasingly important as we move to corpora that cover multimodal information.

Finally, the real win of applying the XML standard to corpora annotation is that it provides access to powerful search and data manipulation tools often developed quite independently of linguistic concerns. Since XML is used as the format of choice for almost all online data these days, the need to manipulate such data is widespread. As a consequence, search and processing mechanisms that can work with XML are increasingly provided as standard functionality even for normal Web browsers. This trend will certainly continue and provides a strong foundation for increasingly powerful corpus manipulation tools capable of working with any combination of data appropriately organized according

to defined XML schemes. This is also an important prerequisite for getting corpus tools out of proprietary formats and tools into more open, and hence freely available and adaptable, resources of use to the community.

Spoken Language Corpora

The view of a corpus as a multilayered set of linked descriptions naturally creates the possibility that other kinds of information be included. Since the architecture itself is essentially open-ended, one can always consider the addition of extra layers. It is here that the essential linearity of the time-based semiotic mode brings considerable dividends for corpus-based investigation.

Moving beyond speech follows almost as a necessary consequence of considering speech data. Speech rarely occurs alone and so, in real contexts of interaction, communication is carried not only by the speech signal but by other modalities as well. The modalities next considered appropriate for representation within multimodal corpora were therefore those evidently important for face-to-face communication, namely gesture and facial expressions. Both of these are now extensively researched in the area of human-computer interaction. Gesture is clearly closely correlated with deictic communicative acts, which play a role in situated shared-task problem solving with artificial agents, and facial expressions are necessary for constructing appropriately behaved human-like avatars. In both cases, it has been recognized that empirical corpus-based research is an essential methodology: We need to see how people manage these modalities and for what purposes in real communicative situations.

Sophisticated models for the linguistically relevant abstractions to be considered in broader collections of data for situated spoken interaction are explored by, for example, Norris (2002, 2004). Additional information concerned with proxemics, spatial position with respect to the environment, and other performance-based variables are also considered. There are as a consequence a range of corpus-based approaches including diverse aspects of the interactive situation as additional tracks of information. And for each of these, there are developing proposals for appropriate annotation schemes that provide the level of abstraction necessary for searching for qualitative patterns (see Kranstedt, Kopp, & Wachsmuth, 2002). These annotation schemes are typically defined in terms of XML schemas, which explicitly set out vocabularies and structures for data annotation within each layer addressed. This explicit definition makes it possible to check large bodies of annotated data for their formal correctness, an important feature since maintaining large corpora is a difficult undertaking.

An overview of recent discussions and results for general annotations that can span several tools for linear-data corpora can be found in the online reports and materials from the 2007 Multimodal Annotation Tools Workshops at <http://multimodal-annotation.org>. An excellent description of tools and their treatment of multimodal data is given in Schmidt et al. (2009).

Transcription

Approaches to corpus preparation that are designed by linguists generally draw on the central linguistic operation of *transcription*. Transcription is the process of enriching basic language data so as to already include qualitative classifications considered appropriate for further theory building. The simplest kind of transcription for spoken data might involve writing peaks of intonational prominence in capital letters; nowadays this would be replaced by a complete annotation scheme reflecting some model of intonation. The relation between transcription and theory building is an intimate one; fundamental discussion is offered by Ochs (1979).

For use in multimodal corpora, it is necessary to transform more informal, descriptive transcription schemes to properly specified annotation frameworks. Here naturally there is a lag, since there are considerably more proposals for transcription schemes than there are implemented annotation schemes; but some of the more developed transcription schemes have been, or are being, reconsidered for driving actual corpus construction. Accordingly, in addition to transcription/annotation frameworks for intonation, there are now also proposals for transcription/annotation schemes for gesture (Kipp, Neff, & Albrecht, 2007), facial expressions, proxemics, gaze, and many more (see Allwood Kopp, Grammer, Oberzaucher, & Koppensteiner, 2007).

Media Analysis

Given that the starting point for many of the natural interaction data described above is provided by video recordings of situations, there is a further natural extension both of techniques and of interest to include not only natural interactions “in the wild” but audiovisual media representations. Here there is an overlap with research performed in media and communication studies, which also have a long tradition of investigating video data for socially significant variations and patterns (see Ludes & Herzog, 2004). From the linguistic perspective, research is pursued that focuses more either on the interactions of individuals presented in the media, as in political interviews or news reporting, or on the communicative possibilities of the medium itself. This latter is a further extension of the domain of multimodality to take in the technical resources employed for constructing audiovisual representations in general, involving such features as camera angles, shots and transitions between shots, camera distances, framing, color balance, perspective, and much more. Early approaches to this from a multimodal corpus perspective can be seen in Thibault (2000), Baldry and Thibault (2005), and Tan (2009). For more general media representations there is also the international standard MPEG-7 (ISO/IEC 15938: *Multimedia content description interface*) for media content: this shows considerable overlaps in aims but has not so far been considered together with the needs of multimodal corpus design. For a thorough consideration of film as a multimodal artifact at the document level, however, see Bateman and Schmidt (2011).

Nonlinear Artifacts: Multimodal Extensions

All of the approaches discussed so far depend upon the linearity property of the semiotic modes involved. Particularly, the *time-based* modes make it possible to combine as many layers or annotation tracks as required by anchoring them against time stamps; some current attempts at standardization even require the existence of time stamps as a precondition for interoperability and translatability of annotations. But semiotic modes relying on the visual channel are not organized around time; they are organized around *space* and spatial relationships (see Kress, 2003).

This presents substantial problems for devising usable markup schemes. A simple geometric representation rarely provides an appropriate level of abstraction for much of what is happening visually, and the range and scope of the semiotic modes carried by the visual channel are still only poorly understood. There are extensive categories of the kinds of information representations that are employed—for example, 2D graphs, animations, films, written text, photographs, drawings, diagrams, flowcharts, maps, and many more—but still little theoretically sound organization for their combination. Written text may play decisive roles for the interpretability of graphics, diagrams may be animated, maps may be annotated with diagrammatic representations (e.g., contour lines), and so on. Moreover, there are additional modes of semiotic organization that are essentially “higher-order” in

that their purpose is precisely to *combine* information offerings from other modes. This, for example, is the function of *layout* as described in detail in Bateman (2008). Whenever language occurs together with such kinds of information, the interrelation of linguistic and nonlinguistic presentations raises important theoretical considerations that can only benefit from corpus-based approaches.

In some domains there are already proposals of a nonlinguistic nature for possible forms of markup and corpus design; for example, the automatic document recognition community has large collections of annotated layouts that are used as *ground truths* for testing recognition algorithms (Antonacopoulos, Karatzas, & Bridson, 2006). Moreover, geographic information science has richly layered representations of spatial data underlying maps; art history has classifications for the content and organization of pictures; and information designers have characterizations for many kinds of diagrams and graphics. When moving into the collection of corpus data involving such artifacts, it will therefore be advisable to be aware of treatments of this kind before defining transcription schemes motivated from within single disciplinary perspectives. Although at present most linguistically informed approaches to such artifacts have not moved beyond proposals for transcription, first moves toward full corpus annotation schemes are described in the *GeM* framework for static multimodal nonlinear documents in Bateman (2008, 2009).

Combinations of Time and Space

It is already evident that there will be an increasing need for *combinations* of all the developments described so far. Many current projects are concerned with the analysis of artifacts such as Web sites, and these can be characterized most effectively as dynamic layouted composite documents. Since Web sites include all of the resources of nonlinear, that is, spatially organized, layout plus the ability to include video and other dynamically displayed data, all of the kinds of annotations/transcriptions mentioned so far may find application there.

The move to include such artifacts within corpus-based research will again demand that tools are able to bring together both linear and nonlinear data types. Moreover, within each data type there will be many distinct kinds of annotation required. In the long run, it may be necessary to have distinct corpus levels, or tiers, for each kind of semiotic mode operative within the data to be analyzed. This then goes considerably beyond distinguishing sensory channels, as argued in detail in Bateman (2010). Some tools, such as ANVIL (Kipp, in press), are now allowing spatial annotations within video data, but this is still exploratory and subordinated to the temporal organization. Further development is required.

Conclusions

Following on the general acceptance within linguistics of the value of performing linguistic research with respect to increasingly large collections of naturally occurring texts, that is, corpora, it has been natural to ask whether these methods and techniques can also be applied to data including those other modes of communication accompanying the linguistic acts. This combination of concerns has led to the design, construction, and use of *multimodal corpora* for informing research that seeks to place language use in richer, multimodally constituted contexts. More abstractly, this represents a gradual change in the boundaries drawn between the “linguistic” and the “paralinguistic”: Ever more phenomena that would previously have been termed paralinguistic, in the sense of accompanying but only weakly influencing linguistic form and expression, are now being moved into the center of concern and so demand methods and approaches by which they can be addressed empirically.

There are also further combinations of modes that have so far received very little study but which are beginning now to be approached using corpus-based methods; for example, the combination/interaction of language and music, as occurs in narrative film, or the combination of eye-tracking behavior and language. As corpus-based empirical approaches move to include such modes of communication, it is crucial that insights from traditions other than the narrowly linguistic are given due consideration.

Corpus-based approaches need therefore to enter into dialogue with such work and not assume that straightforward extensions of the linguistic, or simple “outsider’s” views of the material will be sufficient. The advances to be made here are nevertheless considerable, not only for our understanding of how language works within such multimodal contexts but also for how other communicative modes function. Linguistic, corpus-based methods promise much for placing studies of a broad variety of modalities on a firmer empirical footing—but this can only be done in cooperation and dialogue with those disciplines where those modalities have already been the principal focus of attention.

Multimodal Discourse Analysis

RODNEY H. JONES

Multimodal discourse analysis is an approach to discourse which focuses on how meaning is made through the use of multiple modes of communication as opposed to just language. Although there is a long tradition in semiotics, anthropology, sociology, and cultural studies of engaging analytically with visual texts and other modes, it is only recently that this challenge has been taken up by applied linguists, who, not surprisingly, have traditionally privileged the modes of speech and writing. One reason for the recent surge of interest in multimodality in applied linguistics is the increasing importance of multimodal representation in everyday life with the rise of digital technologies. Multimodal texts, however, are far from new. In fact, before the development of the printing press, most texts were “illuminated” in some way, with considerable attention paid to things like illustrations and calligraphy. Another reason for the development of multimodal discourse analysis is the concurrent development of the technologies—specifically digital video cameras and computer editing and analysis software—which have made this kind of analysis possible.

It should be stressed at the outset that multimodal discourse analysis is not the study of a special kind of discourse, that is, “multimodal” discourse. Rather, it is the engagement in the multimodal dimension of all discourse. As Scollon and Levine (2004, pp. 1–2) point out,

language in use, whether this is in the form of spoken language or text, is always and inevitably constructed across multiple modes of communication, including speech and gesture not just in spoken language but through such “contextual” phenomena as the use of the physical spaces in which we carry out our discursive actions or the design, paper, and typography of the documents within which our texts are presented.

In other words, multimodal discourse analysts, for the most part, occupy a position which actually puts them at odds with most of their colleagues in applied linguistics: the position that simply analyzing language (i.e., speech or writing) as it is used in a particular situation results in a fundamentally distorted picture of what is actually going on in the situation. While language might play a role in what is going on, it might not be the most significant mode, and there may indeed be situations or texts of interest to discourse analysts that may not involve the use of language at all.

The concept of “mode” in multimodal discourse analysis should not be confused with the concept of “modality” in grammar (which refers to the expression of possibility and obligation in statements), or with the concept of “mode” in Halliday’s tripartite model of *context* (consisting of field, tenor, and mode), in which mode refers to the “channel” of *linguistic* communication (i.e., speech or writing). When multimodal discourse analysts speak of mode they usually mean a conventionally recognized “semiotic system with an internal grammaticality, such as speech, color, taste, or the design of images” (Scollon & Levine, 2004, p. 2). *Modes* are also clearly distinguished from *media*, which are the physical or material carriers of modes (e.g., paper, telephones, television, computer screens, and the like). For example, while dress would be considered a mode (a system governing the combination of various semiotic elements involving color, shape, texture, and their placement on a human body), clothing is a medium, the physical means through which this

system is expressed. At the same time, there is an intimate and complex relationship between modes and media: the functions and significance of various modes evolving in relation to the development of technologies and the social practices governing their use in particular sociohistorical contexts (Kress & van Leeuwen, 1996).

The notion of mode, however, especially if it is seen as a reified, bounded semiotic system with stable characteristics, is not unproblematic, especially in situations where the development of new media results in the blending of modes (as computer technology has done in the case of speech and writing; see Goddard, 2004). It is more useful to regard modes as a heuristics rather than as stable categories or systems. As Norris (2004, p. 11) points out, while modes are unavoidably construed as distinct entities, they are in reality “not bounded units. A mode is a loose concept of a grouping of signs that have acquired meaning in our historical development.”

Since its inception as a widely recognized approach to discourse in the late 1990s, multimodal discourse analysis has focused on two broad areas of research—the study of multimodality in *texts* like magazines, comic books, films, works of art, and Internet Web pages, and the study of multimodality in *interaction*—each drawing on rather different traditions in linguistic and social science research. These two lines of research, however, sometimes interact, especially as “texts” like Web pages become more interactive (see, e.g., Kress, 2003), and in situations like classroom interaction in which the manipulation of multimodal textual objects plays an important role in interaction (see, e.g., O’Halloran, 2005).

Work on the analysis of multimodality in texts has its roots in the systemic functional linguistics of Michael Halliday, especially as it was applied in the late 1970s to the development of *social semiotics* by the critical linguistics group at the University of East Anglia. Perhaps the most influential proponents of this approach to multimodal discourse analysis are Gunther Kress and Theo van Leeuwen, who, in their 1996 classic *Reading Images: The Grammar of Visual Design*, propose that images can be analyzed according to their ideational, interpersonal, and textual functions by applying conceptual tools from functional grammar such as transitivity and modality. This project was later taken up by others and applied to a range of other modes across a wide range of media and social situations (see, e.g., O’Halloran, 2004; Royce & Bowcher, 2006). Of particular note are O’Toole’s (1994) examinations of paintings, sculpture, and architecture, and O’Halloran’s (2005) application of this model to the analysis of mathematical discourse. Later work within this framework has moved from considering how meaning is expressed in specific modes to more of a focus on how modes relate to one another intersemiotically. This approach has also evolved in Kress and van Leeuwen’s work, especially in their inclusion of the practices of production and consumption of multimodal texts as fundamental issues for analysis.

The sometimes uncritical application of principles developed in systemic functional linguistics to the analysis of nonlinguistic modes that has characterized a portion of this work, however, has attracted some skepticism. Bateman and his colleagues (Bateman, Delin, & Henschel, 2002), for example, point out that analytical principles like “given and new” have been adopted from the analysis of temporally organized modes like writing to the analysis of visual layout without sufficient empirical evidence that this is indeed an accurate account of the way people process visual information.

The second broad area of research in multimodal discourse analysis focuses on the analysis of socially situated interaction. The perspectives, methods, and agenda of this strand of research have grown out of a very different academic tradition than the one described above. Rather than systemic functional linguistics, this approach has been more influenced by work in linguistic ethnography, anthropology, and psychiatry, especially the “ecological perspective” on communication developed by Schefflen, Birdwhistle, Bateson, and others working in the Palto Alto research group in the 1950s (see, e.g., Ruesch &

Bateson 1951/1968; Birdwhistle, 1970; Schefflen, 1974). It has also drawn heavily on work in conversation analysis and interactional sociolinguistics (see, e.g., Goodwin, 2000), “non-verbal communication” (see, e.g., Kendon, 1990; McNeill, 1992), and mediated discourse analysis as developed by Scollon and his colleagues.

Perhaps the best exemplar of this approach is Sigrid Norris, whose book *Analyzing Multimodal Interaction* (2004) lays out a systematic framework for analyzing the multimodal nature of face-to-face interaction. Among the important concepts included in this framework are the notions of *modal density*—the relative salience of a mode in relation to other modes—and of a *foreground and background continuum* along which participants’ simultaneous engagement with multiple modes can be mapped. Another significant contribution of Norris’s work is her examination of the relationship between multimodal communication and the negotiation of identity in interaction.

There has been other work that combines an interest in multimodal texts with a concern with how those texts are shaped and reshaped in the context of ongoing interaction. Of particular note is the work of Rick Iedema (2001), who takes the position that multimodal analysis must be complemented by a more dynamic perspective on semiosis which examines how social interaction helps to shape the ongoing emergence of multimodal meaning. Iedema’s main contribution to the field of multimodal discourse analysis is his concept of *resemiotization*, which he defines as the dynamic process through which meaning changes as it becomes instantiated in various configurations of modes and media along the trajectories of various social practices. One example Iedema gives is the way meanings associated with the building of a new wing of a hospital change as they are expressed orally in planning meetings, in the written language of reports, in the graphic language of architectural drawings, and in the material instantiation of bricks and mortar.

Within both of these broad approaches, and in work which attempts to combine them, is the potential to contribute to the understanding not just of texts and interactions but also of social practices, ideologies, and the social structures and psychological constructs that underpin them. Thibault (2004), for example, draws on systemic functional linguistics to formulate a cognitive model of multimodality which explores how biological and social factors interact to affect meaning, and Scollon (2007), drawing on mediated and critical discourse analysis, considers ways in which judgments about the truth, reality, and reliability of messages are affected by the modes and media in which they are physically produced as objects in the world. Multimodal discourse analysis has also made particularly important contributions to education and literacy studies, especially regarding the ways digital multimodal texts are affecting educational practices and the way students learn (Kress, 2003; Jewitt, 2006).

Multimodal discourse analysis continues to advance both theoretically and methodologically with the development of new ways of collecting and transcribing data and of compiling and analyzing large corpora of multimodal texts and interactions (Norris, 2004; O’Halloran, 2004; Baldry & Thibault, 2005; Baldry, 2007).

Multimodal Interaction Analysis

SIGRID NORRIS

Multimodal interaction analysis (Norris, 2004) is a holistic methodological framework that allows the analyst to integrate the verbal with the nonverbal, and to integrate these with material objects and the environment as they are being used by individuals acting and interacting in the world. In short, multimodal interaction analysis allows a researcher to study real people interacting with others, with technology, and with the environment. Multimodal interaction analysis, to give a few and diverse examples, has been utilized to study topics such as ethnic and personal identity (Norris, 2007, 2011b), power and male domination (Norris, 2007), interactions in public relations offices (Sissons, 2011), rhythm in everyday interactions (Norris, 2009), traditional Indian painting practices (Frommherz, 2011), advertising billboards (White, 2010, 2011), and computer-mediated communication (Örnberg Berglund, 2005).

The point of view taken in multimodal interaction analysis is that all actions in fact are interactions and that all of these (inter)actions are linked to people (referred to as social actors in multimodal interaction analysis)—no matter whether you are investigating the real or the virtual world, someone buying ice cream, or a software program. When thinking about buying ice cream it is obvious that a social actor is buying and another social actor is selling the ice cream. It is also obvious that a social actor (or more likely a whole number of social actors) made the ice cream using ingredients, tools, and machines. When looking at a software program, we look at it in the same way: a social actor is using it; but a social actor (or rather, again, a number of social actors) produced the software, embedded fonts, color schemes, and the like. Social actors are the key element in multimodal interaction analysis. Multimodal interaction analysis emphasizes that all social actors act by using cultural tools—from language and gestures to coffee makers and computers. On the one hand multimodal interaction analysis (following mediated discourse analysis) argues that social actors cannot act without using some cultural tools; and on the other hand multimodal interaction analysis claims that cultural tools do not exist without social actors producing, using, and re-producing them. Because of these two interlinked claims, there is a constant tension in (inter)action between social actors and the cultural tools that they are using.

Background: Multimodal Interaction Analysis

The framework primarily grew out of mediated discourse analysis (Scollon, 1998, 2001) in connection with interactional sociolinguistics (Goffman, 1959, 1963, 1974; Gumperz, 1982; Tannen, 1984) and multimodal analysis (Van Leeuwen, 1999; Kress & Van Leeuwen, 2001). Multimodal interaction analysis allows the integration of all communicative modes, where communicative modes are defined as systems of representation with rules and regularities attached to them (Kress & Van Leeuwen, 2001) as they are being used (Norris, 2009). The last part of the definition, “as they are being used,” is of particular interest to multimodal interaction analysis, emphasizing a focus on social actors acting. In other words, multimodal interaction analysis is interested in systems of representation in action, as part of action, or as a result of action; multimodal interaction analysis is not, however, interested in

systems of representation as entities. This focus on action is in line with mediated discourse analysis.

Unit of Analysis

In multimodal interaction analysis, as in mediated discourse analysis, the action is the unit of analysis. An action is defined as a social actor acting with or through mediational means (Wertsch, 1998). Within the action we find the constant tension alluded to above between social actor and cultural tool. Certainly, not all actions are of the same kind; the three general demarcations are as follows.

First are the lower-level actions, which are the smallest pragmatic meaning units of communicative modes, such as an utterance for spoken language, a gesture unit for the mode of gesture, or a postural shift for the mode of posture. These lower-level meaning units are of interest to multimodal interaction analysis as they allow for micro-analyses.

Second, we investigate higher-level actions, which are made up of an abundance of chains of lower-level actions; for example, a conversation is made up of chains of utterances, chains of gestures, chains of postural shifts, and so on. While a higher-level action such as a conversation is on the one hand produced through these chains of lower-level actions of utterances, gestures, or postural shifts, the lower-level actions on the other hand only come about because the higher-level action is being produced. Thus lower-level and higher-level actions co-create each other. While there is a bottom-up and simultaneously a top-down development in (inter)action between the various levels of action, it is, however, usually the higher-level action (such as a conversation) that social actors are actively focusing upon.

Third, we investigate frozen actions, which are actions entailed in objects and the environment. For example, the action of building is frozen in a house, or the action of making coffee is entailed in the cup of coffee itself, just as the action of producing a software program is embedded in the actual software program.

While there are three units of action, and any or all of them can be taken as the starting point of an analysis, there are, of course, many different levels of action. Some are smaller than the lower-level actions and some are larger than the higher-level actions discussed above. A lowest-level action might be an in-breath, and a higher-order, higher-level action might be a marriage. What is important is the fact that each action, no matter how small or how large, has a beginning and an ending point. However, neither the beginning nor the ending points of the higher-order, higher-level actions may in fact be part of the data collected for an individual study. Thus, we know theoretically that there is a beginning and an end when investigating higher-order, higher-level actions, while the actual starting and ending points may be unclear. Certainly, the lower the levels of action under investigation are, the clearer the beginning and ending points become. For example, an in-breath begins at some point and ends at another, a gesture begins at some point and ends at another, and a dinner begins at some point and ends at another.

Modal Density Foreground–Background Continuum of Attention/Awareness

Actions are phenomenological and visible or audible. But, rather than dismissing psychology, multimodal interaction analysis embeds the notion of attention/awareness into the framework. Attention and awareness are viewed as two sides of (almost) the same thing: When a social actor pays attention to an action, the social actor is also aware of it. However, attention and awareness are not always perceivable in the same way. Just think of a social

actor cutting a Christmas ham for the first time. The social actor necessarily has to pay close attention and is also highly aware of the action. But now think of a social actor (we will call her Petra) sitting in a café, holding a sleeping baby, and chatting with a friend about a problem. Petra pays close attention to the friend and the problem that they discuss, and, at the same time, she is holding the sleeping baby in her arms. She pays no attention to the baby (or so it appears), but when you think about it more, you will find that she has to be (and necessarily is) aware of the sleeping child and has to (and does)—in turn—pay some attention to it, even if only a little. Thus, paying attention to and being aware of an action constitute one state, even though sometimes we will be able to perceive this state by investigating the paying of attention, while at other times we are able to perceive it by investigating the state of awareness necessary to perform the action.

Horizontal Simultaneity of Actions

When looking at interaction in this way, we discover that a social actor is often involved in more than one higher-level action at a time: The social actor in the example above is interacting with her friend and at the very same time is interacting with the baby. She thus (co-)constructs two higher-level actions with two different social actors simultaneously, but on different levels of attention/awareness. This notion of social actors (co-)constructing simultaneous actions was groundbreaking and only possible (a) because of the multimodal lens that multimodal interaction analysis utilizes, and (b) because multimodal interaction analysis is interested in how actions are constructed in social actors' attention/awareness levels. While a social actor can always only focus on one higher-level action at a time, social actors can pay decreasing attention/awareness to many more higher-level actions. The modal density foreground–background continuum in Figure 1 is used as a heuristic tool to illustrate such simultaneous (co-)construction of higher-level actions by one social actor.

While the simultaneity of the (co-)construction of higher-level actions and the attention/awareness levels appears plausible by itself, multimodal interaction analysis uses a scientific notion, called modal density, to delineate the higher-level actions and to place them relationally on a heuristic social actor's foreground–background continuum of attention/awareness. Modal density is the complexity or the intensity that the social actor utilizes to produce a higher-level action. Modal density in simultaneous higher-level actions can be high, medium, or low, or anything in between. When thinking once more of Petra sitting with her friend and the baby in the café, we can see that she is utilizing many

Figure 1 Petra's attention/awareness levels: She pays close attention to the higher-level action of chatting with her friend and simultaneously pays some attention to the higher-level action of holding a sleeping baby

modes highly intertwined when speaking with her friend: She uses the modes of spoken language (talking about the problem), gesture (moving her hands/arms every so often), gaze (looking at her friend and looking away at certain intervals), posture (sitting in such a way that she can easily talk with and understand her friend), proxemics (sitting close to her friend), and objects and object handling (sitting in a chair, in front of a table in a café, and drinking coffee out of a cup). There are many modes at play in this interaction which indicate to the onlooker and to the social actors themselves that Petra pays close attention and is highly aware of the higher-level action that she (co-)constructs with her friend.

When we now think about the modal density in her interaction with the baby, an interaction that she appears to pay no attention to at first sight, we find that she uses the modes of proxemics (holding the baby close to her), posture (sitting in such a way as to easily hold the baby), and touch (holding the baby close to her torso and in her arm) in this interaction. While these modes are closely interwoven, they do not build the same modal density as the many interwoven modes used in the conversation. This example is straightforward and easy to analyze, but there are many more complex simultaneous interactions which can only be analyzed through this very notion of modal density.

Multimodal interaction analysis also investigates the psychological levels of attention/awareness besides the phenomenological ones (Norris, 2007). The idea behind this is the following: A social actor has feelings when performing an action in their everyday life, and, while (co-)constructing one action with other social actors or the environment, the social actor has not forgotten what they did before, and what is even more important, the feelings often linger. Because of this lingering of feelings, prior higher-level actions often have an impact upon current ones. It is the lingering of feelings that indeed becomes phenomenological when social actors are studied over time, and it is this phenomenological appearance of the psychological states that is of interest to multimodal interaction analysis (Norris, 2007).

Vertical Simultaneity of Actions

Just as social actors are involved in more than one action at a time horizontally, so social actors' actions are embedded in more than one layer of discourse at a time vertically. Generally, we distinguish between three layers of discourse: the central, the intermediary, and the outer (Norris, 2011b).

When taking a closer look at Petra in the example above, we find Petra's lower-level actions and with them the higher-level action of speaking to her friend as well as the higher-level action of holding the sleeping baby, producing the central layer of discourse. This is the immediate layer of discourse, in which Petra as well as her friend and the sleeping baby are involved. These are the immediate, one-time actions performed.

At the very same time, Petra's action of speaking with her friend and also the action of holding the sleeping baby produce an intermediary layer of discourse. This is formed by Petra in connection with and through her networks, enacting certain long-term actions. In other words, perhaps Petra speaks with this friend much in the same way she speaks with other friends (illustrating certain knowledge in Petra's network on how she acts), or perhaps Petra speaks with this friend in a café as she never has before (thus negating the network expectation with regard to Petra's usual actions). However, only close research on Petra within her network can give a researcher the intermediary layer of discourse that Petra produces with this action. Similarly, of course, we can see that the action of holding the baby is also embedded in an intermediary layer of discourse. Maybe Petra is a babysitter and takes the babies she watches to meet her friends; or maybe she is a mother, who takes her baby everywhere. In either case, Petra enacts this action of holding the sleeping baby on an intermediary layer of discourse as well as on the central layer explained above.

Thus, on the intermediary layer of discourse, these one-time actions performed locate Petra in her network as a social actor who performs these kinds of action on a regular basis (or not).

Besides the central and the intermediary layers of discourse, Petra also enacts her action of speaking with her friend and the action of holding the sleeping baby producing and reproducing an outer layer of discourse. This is formed by the larger society, and is enforced by the extended networks that a social actor is part of and by institutions that the social actor engages with. Let us assume that Petra is in fact the mother of the baby and frequently meets this and other friends at cafés, taking her baby along. Petra thus may act in accordance with the institution called family. Similarly, when thinking of institutionalized layers of discourse, we may find that Petra speaks and acts in accordance with society's expectation of how a woman of her age is supposed to speak and act. An examination of the outer layer of discourse (institutionalization of actions and societal forces upon the actions performed) in connection with the intermediary (network forces upon the actions performed) and the central layers (micro-interactional forces upon the actions performed) may shed light upon Petra's possibly diverse higher-level actions that she is combining at this and other times.

Using Multimodal Interaction Analysis as a Method

Multimodal interaction analysis is used to analyze varied interactions in everyday life, from individuals having conversations to doctor–patient interactions and people using technological tools such as cell phones or computers in the workplace (Norris, 2004). It is used to investigate teacher–student interactions from first-grade classrooms (Norris, 2003) to individual music lessons (Norris, 2004) and stable and horseback riding lessons (Norris, 2009, 2011a).

Multimodal interaction analysis is also used for the analysis of identity in everyday life, and several methodological concepts have been established, particularly for research into identity production, relating directly to the methodological concepts discussed above. As an example, we can speak of the production of identity elements when investigating the construction of higher-level actions. Or we can speak of immediate, continuous, and general identity element production when investigating central, intermediary, and outer layers of discourse.

Multimodal interaction analysis thus allows the analysis of human (inter)action, shedding new light upon old questions such as: How do social actors accomplish successful communication? How are certain actions performed by social actors? How is personal or national identity produced by social actors acting in today's complex world? What are the roles that objects and the environment play in particular (inter)actions? Or: How many higher-level actions can a social actor perform simultaneously? Knowing that social actors' feelings from one (inter)action impact following (even unrelated) actions, what kind of an impact do lingering feelings have on other actions? But the most important question that multimodal interaction analysis asks, no matter what topic is being investigated, is: How can we use the knowledge that we gain through our multimodal investigation to alleviate some of the miscommunication and the difficulties that social actors encounter in their everyday lives? In any case, multimodal interaction analysts attempt to better the lives of those that we study.

Multimodal Literacy

LESLEY LANCASTER

Introduction

The terms “multimodality” and “literacy” have been associated as part of a critique of conventional accounts of literacy, reviewing traditional associations between spoken language and writing. “Multimodal literacy” is a term that has evolved from this association, and focuses on the diversity of modes and materials involved in the production and interpretation of texts. It is informed by a semiotic perspective where literacy is viewed as the design and construction of signs, using available material, bodily, and technological resources to combine forms and meanings (Jewitt, 2008a, p. 1). This takes place in social and cultural contexts, with the situation of sign-makers informing the textual choices made. It is a relatively new and developing field of study: Harste, Woodward, and Burke identified writing as a multimodal process in 1984 (p. 208), and *Multimodal Literacy*, edited by Jewitt and Kress and published in 2003, forged a new direction in literacy research. The papers in that book described literacy as a process of sign-making across curricular disciplines, with literate meanings being made, distributed, and interpreted in different representational and communicative modes. Theory and practice developed during the 1990s and beyond (Kress, 1997; Pahl, 1999; Kress & van Leeuwen, 2001), establishing multimodal literacy as a significant area of research, with considerable implications for policy and pedagogy in educational settings. A special issue of the *Journal of Early Childhood Literacy* on multimodal literacy reflected the growing acceptance of research into multimodality and literacy and its influence on educational practice (Lancaster & Rowe, 2009). Recent changes to ways in which we communicate and represent meaning wrought by new technologies, and the increasing centrality of the Internet to social and economic life, have given considerable impetus to a shift of emphasis from research into literacy as language-based practice, to research into literacy as process, practice, and representation in a number of different modes (Kress, 2003).

Relationships Between Language and Literacy

Conventional approaches to literacy view writing as a linguistic mode, concerned with the transcription of speech, and suggest that it evolved from the outset to represent language (Havelock, 1976). Many pedagogical programs for literacy teaching continue to reinforce this view by prioritizing the early teaching of sound–letter correspondences as an essential starting point for literacy learning. However, other scholars suggest that writing developed originally to communicate information (Harris, 2000), and that writing systems evolved from early counting devices and auditing systems (Schmandt-Besserat, 2002). Objects and transactions were visually represented, and Schmandt-Besserat suggests that many of the conventions of early forms of writing, such as its linear organization, and its semantic use of the form, size, order, and placement of graphic signs evolved from this. Hence visual and material forms of writing provided a conceptual model for understanding the structures of language and the representation of speech, rather than the other way round.

In this regard, writing can be seen as essentially multimodal, in that it is able to visually represent a temporal sequence of events in a spatial form. Writing has always shown what needs to be told; Kress distinguishes between *telling the world* and *showing the world* (2003, p. 140), pointing to the increasing importance and dominance of visual images in domains of public and private communication (p. 1). This extends the relationship between multimodality and writing to include the multimodality of texts, where writing is variously combined with visual images and, increasingly on computer screens and Web pages, with visual and moving texts, and with sound and music. Meaning is distributed across modes, with each mode making a partial contribution to the total meaning of the text (Jewitt, 2008b, p. 247). Different modes have different “affordances,” offering different representational features and qualities to text producers, and different meaning-making opportunities appropriate to the textual environment.

Multimodal Texts

The acknowledgment that texts represent and communicate meaning in multiple modes is to some extent a recognition of a state of affairs that has always existed. People have always mixed modes depending on the purpose and requirements of the text: for example, combining words with diagrams, drawings, and other images, and using various forms of graphic emphasis such as variations in font and layout to communicate and represent meaning (Bearne & Wolstencroft, 2007, pp. 1–3). Digital technology has vastly extended the potential for combining modes and for creating new kinds of literate texts. Screens, for example, are now ubiquitous in many public places, with news coverage that involves talk, still and moving images, and writing continuously streamed along the bottom of the screen; cell phones transmit images, sound, color, music, digital images, and writing in multiple combinations. These new communicational environments have forged new textual relationships between modes (Jewitt, 2008b, p. 257), and have unsettled traditional ones. Texting and many kinds of e-mail writing, for example, have more in common with the informality conventionally associated with talk than they do with many other kinds of writing.

Multimodality reconceptualizes commonsense understandings of literate texts, suggesting that they cannot be regarded as synonymous with written texts, and may involve writing only partially. However, this reconceptualization does not extend to metaphorical uses of the term “literacy,” whereby competence and skill in any field of activity is regarded as a kind of literacy, as in the case of “emotional literacy.” Multimodal literacy also redefines literacy within schools, and reconceptualizes what can be considered a literate text within a pedagogical context. Lemke (2000) considers the literacy demands of chemistry and physics in post-compulsory classrooms, and the impossibility of coding ideas solely in linguistic and written modes. Stein (2003) examined a body of stories produced by young children in South Africa, showing how their combined use of drawing, writing, spoken dialogue, and production of three-dimensional figures extended textual boundaries in a manner that was significant for the ways in which they learned. Wohlwend (2007) shows how kindergarten children pretend new technology into being in “print-centric” classrooms where new ways of communicating meaning are not welcomed. Some of the exemplars discussed by these scholars would not traditionally have been accepted as literate texts, but are examples of ensembles of signs, where the meaning of the whole is distributed across a number of modes and media.

Changing Relationships Between Producers and Texts

The association between multimodality and literacy has led to a reconsideration of the relationship between producers, readers, and texts, and between the processes of production and dissemination (Jewitt, 2008b, p. 243). This challenges the view that literacy has settled genres and fixed forms over which readers and producers have no control, and shows that literacy learning requires complex understandings of the interrelationship between bodily, material, and graphic modes of making meaning in social situations. The New London Group (Cope & Kalantzis, 2000) describes this process as a matter of design, whereby learners and producers use available material and discursive resources in order to continuously shape and transform literate forms and meanings. Kress's work on early literate practices produced groundbreaking evidence showing that children have a high level of control over the process, enabling them to "make meaning in an absolute plethora of ways, with an absolute plethora of means" (1997, p. xvii), and that in their production of signs they employ the strategy of choosing and "using the best, most apt available form for the expression of a particular meaning" (p. 17).

Multimodal literacy has also influenced thinking about relationships between mind and body in the process of the teaching and learning of literacy, recognizing it as an embodied process. Flewitt (2005) and Lancaster (2007) have highlighted the significance of different bodily modes of interaction, such as gesture and gaze, in young children's early production of texts. These are used as resources to communicate meanings interpersonally to adults and other children copresent, and might also be incorporated into the structure of the sign, for example by enacting part of a meaning by bodily or vocal means. Bodily modes are also central to classroom interactions. Studies of multimodal practices in teaching in high school classrooms in the United Kingdom (Kress, Jewitt, Ogborn, & Tsatsarelis, 2001) reveal the complex ways in which gesture, gaze, action, interaction with objects, body posture, speech, and writing interact during the production of school subject knowledge.

Theoretical Influences

Social Semiotics

Michael Halliday's formulation of language as social semiotic (1978) had a foundational role in developing a practical and theoretical association between multimodality and literacy. Halliday defines mode as a channel of communication, with language and writing as distinct communicative modes. Children grow up in diverse social and semiotic environments, encountering networks of meanings in different modes that constitute their culture or cultures as they "learn how to mean" (p. 100). Hodge and Kress (1988) developed this concept, emphasizing the need to take account of the social place and history of children as sign makers, and of the social environments in which their signs are made. Becoming literate is a semiotic process, these authors argue, involving the production of signs, and it is also a key point in the formation of children as ideological individuals within society. There is a strong emphasis on visual meaning in the children's texts they present and discuss, which incorporate diagrams, images, and attention to layout, anticipating future developments in the field.

New Literacy Studies

New literacy studies calls into question the singular notion of literacy, preferring to use the term "literacies," thereby reflecting the diversity of situated literacy practice and distinguishing it from "autonomous" models of literacy, detached from the social environments

in which they are produced. Drawing extensively on ethnographic theory and practice, situated literacy is concerned with literacy events and practices that are situated in people's everyday lives and with their variation across cultural space and time. Like social semiotics, new literacy studies regards literacy as ideological activity, involving a diversity of practices within different communities. The field has produced some classic studies, including Heath's of the literacy practices of working- and middle-class residents in the rural Carolinas (1983). More recently the field has looked at literacy practices in online environments and digital spaces. Both new literacy studies and multimodal literacy take the view that it is impossible to isolate literacy practices from situated semiotic activity taking place in homes and communities. While these approaches have a great deal in common, multimodal literacy tends to focus more strongly on the production and use of texts, and new literacy studies on how texts are used in different environments (Street, Pahl, & Rowsell, 2009, p. 194).

New London Group

The New London Group was established in 1994 to consider the future of literacy teaching in the context of rapidly changing economic and semiotic circumstances engendered by global capitalism, and the new demands made on people as makers of meaning. This group too eschew an autonomous approach to literacy, using the term "multiliteracies" to reflect the multiple modes and media of communication that they are concerned with, and the pedagogical significance of cultural and linguistic diversity. The group maintain that literacy and literacy pedagogy need rethinking in light of this increasing diversity and global connectedness (Cope & Kalantzis, 2000). The work of the group is also informed by an agenda of social justice: They argue that it is only through such changes to literacy practices and pedagogy that students can obtain the kinds of skills and knowledge required to achieve their aspirations in a changing world. This includes acknowledgment of the essential relationship between literacy and multimodality, and the need to take account of the rapidly changing digital landscape that informs the production of texts.

Future Directions

The association between multimodality and literacy is one that is likely to become increasingly salient as writing is progressively used as one resource of many in the production of 21st-century texts. This circumstance is driven by the development of increasingly sophisticated and versatile digital media for the communication and representation of meaning. New models of literacy will be needed that can accommodate the changing roles of writing, the diversity of tools and media used in its production, and the implications of these for literacy pedagogy and practice in all educational settings.

Multimodal Teaching and Learning

CAREY JEWITT

Multimodality

Multimodal perspectives on teaching and learning build on the basic assumption that meanings are made (as well as distributed, interpreted, and remade) through many forms and resources of which language is but one—image, gesture, gaze, body posture, sound, writing, music, speech, and so on (Kress & van Leeuwen, 2001; Jewitt, 2009). That communication is multimodal is not, however, *new*—people have always used image and non-verbal forms to communicate. The multimodal character of communication, teaching, and learning are increasingly commonplace across a range of disciplines (e.g., anthropology, education, design, linguistics, media and culture studies, musicology, sociology). Educational studies have been undertaken within anthropology and sociology on the role of gesture and gaze in the organization and conduct of face to face interaction and social interaction in learning environments (Goodwin, 1995; Erickson, 2004), as well as research on gesture, inscriptions, and material arrangements in the science classroom (Roth, 2001). This work shares the focus of the multimodal research on naturally occurring teaching and learning practices although it retains a primary interest in the role of talk within the multimodal ensemble, and in the case of Roth an interest in cognition. My focus here is on multimodal teaching and learning from a social semiotic perspective, which is informed by linguistic theories, in particular the work of Halliday's (1978) social semiotic theory of communication and developments of that theory by Hodge and Kress (1988).

Detailed studies on specific modes have helped begin to describe non-linguistic semiotic resources, their material affordances and organizing principles, such as Kress and van Leeuwen's seminal work on images (1996), and other key works that contribute to an evolving "inventory" of semiotic modal resources. The concept of *modal affordance* refers to what it is possible to express and represent easily. How a mode has been used, what it has been repeatedly used to mean and do, and the social conventions that inform its use in context, shape its affordance. Multimodal research shows that people draw upon their available modal resources to make meaning in specific contexts. Further, these resources come to display regularities through everyday patterns of use. The more a set of resources has been used in the social life of a particular community, the more fully and finely articulated its regularities and patterns become. Consequently, any given mode is contingent upon fluid and dynamic resources of meaning, rather than static skill replication and use.

Alongside the assumption that all modes in a communicative event or text contribute to meaning, models of multimodality assert that all modes are partial. That is, all modes, including the linguistic modes of writing and speech, contribute to the construction of meaning in different ways. Therefore no one mode stands alone in the process of making meaning, rather each plays a discrete role in the whole. This has significant implications in terms of epistemology and research methodology: Multimodal understandings of teaching and learning require the investigation of the full multimodal ensemble used in any communicative event. The imperative, then, is to incorporate nonlinguistic representation into understandings of what teachers and students say and write in the contemporary

classroom. This has implications for contemporary theorizations of literacy, pedagogy, curriculum, and learning in the school classroom.

Given emergent local foci of multimodal practices, research in teaching and learning is generally small-scale, ethnographic, and case-based—with limited analysis of the impact on teaching and learning. Much of this work is descriptive, offers detailed inventories of the resources used by students and teachers, shows how these are developed into multimodal ensembles, and draws out the implications for teaching, the construction of curriculum knowledge, literacy, and learning.

Teaching

Multimodality has been taken up to explore teaching practices in a variety of contexts and to inform models of teaching (New London Group, 1996; Cope & Kalantzis, 2000). Multimodal research has examined the ways in which teachers orchestrate a range of modal resources, gesture, gaze, position, posture, action with books and boards, and talk in the classroom. It has examined the ways in which language policy, student identities, official curriculum, and examination and school knowledge are mediated through multimodal communication in the classroom (Kress, Jewitt, Ogborn, & Tsatsarelis, 2001; Bourne & Jewitt, 2003; Kenner & Kress, 2003; Kress et al., 2005). Comparative multimodal analysis has also examined how these patterns vary across systems and cultural contexts (Battachary et al., 2007). Such work has shown that significant aspects of teaching work is realized through a range of modes.

Studies of multimodal practices of science and English classrooms in the UK has shown that this holds true even in a curriculum context such as English where talk and writing dominate the classroom (Kress et al., 2005). The Multimodal Production of School English project involved detailed video recording and observation of nine English teachers in three inner-London schools, as well as interviews with teachers and students and the collation of texts made and used in the classroom. The project shows the complex ways in which image, gesture, gaze, interaction with objects, body posture and writing, and speech interact in the classroom production of school subject knowledge. The School English project highlighted how students and teachers coproduce notions of ability, resistance, and identity in the classroom through their non-verbal interaction. The way in which classroom displays, space, furniture, and artefacts were designed to realize versions of English as a school subject was also documented. This research showed that the work of interpreting school English is beyond language, and requires the ability to make sense of a range of modes and the relationships between them. It also highlighted the complex multimodal identity work that students engage with in the classroom.

Significant research has been conducted on the “technologization” of teaching which explores and theorizes the nature of image and text relations across the curriculum, and relationships between books and computer-based versions of texts, as well as the interpretation and generation of new forms of multimodal and digital narratives and literacies. This work often describes new forms of literacy in an attempt to remap the terrain of the multimodal landscape, and identify the kind of practices that help teachers and students move across it. This has led to efforts to augment the technical language of linguistics (e.g., genre, grammar, and discourse), in order to describe and explain the semiotic contribution of each mode to multimodal texts. Substantial theoretical descriptions of the dynamics of interaction between image and language have been offered, for example, by the early work of Kress and van Leeuwen (1996) and Lemke’s work on science textbooks (1998), and more recent work by Kress and Bezemer (2008) on contemporary curriculum materials that investigates the learning gains and losses of different multimodal ensembles. Multimodal

work raises important issues about how image, word, and design of modes are understood as available resources for meaning-making in the classroom.

Curriculum Knowledge

Knowledge is, from a multimodal perspective, understood as shaped through the choice of one mode over another, as each mode introduces consequent constraints and possibilities for the representation of curriculum knowledge. The teacher's choice of mode is therefore viewed as a process of pedagogic multimodal design, matching the target knowledge with the particular modal affordance in a given situation. Image and other non-linguistic modes come to take on specific situated roles in the construction of curriculum knowledge. For example, representation of a cell in the science classroom as an image or through writing, in colour or black and white, as a three-dimensional model or an animated sequence on a CD-Rom or webpage, makes available and foregrounds different aspects of the concept of cell. Each of these representational forms makes different demands on the learner (Kress & van Leeuwen, 2001). Different modes have differential potential effects for learning, the shaping of learner identities, and how learners find pathways through texts. The choice of mode, then, is central to the epistemological shaping of knowledge and ideological design. What can be done and thought through images, writing, or action differs in ways that are significant for learning. In this regard, the longstanding focus on language as the principal, if not sole, medium of instruction can at best offer a very partial view of the work of communicating in the classroom. Further to this, the technology of production, dissemination, and communication that is chosen is key to the shaping of curriculum knowledge.

Multimodal research enables the investigation of the role that different semiotic modes or sign systems have in classroom communication. Across both print and digital media the relationship between image and writing in educational materials (e.g., textbooks, websites, etc.) appears to be in historical transition (Jewitt, 2008; Kress & Bezemer, 2008). This change relates both to quantity and, perhaps more importantly, to the quality and function of images in a text (Jewitt, 2002). Images are no longer illustrative of writing on the page or screen; rather, a phenomenon may now be introduced and established visually. Onscreen resources frequently place image, action, sound, and other modes (including the body) in new intertextual relationships that redefine and foreground space and time (Leander & Wells Rowe, 2006). The relationship between modes in learning materials raises important questions for learning, which require a better understanding of the gains and losses realized through the representation of curriculum concepts in one mode rather than another (Kress & Bezemer, 2008). This raises serious issues about teachers' access to materials (e.g., websites, CD-ROMs, games and simulations, textbooks, and worksheets) and technologies, and how these are used in the classroom.

Learning

Understanding the communication landscape of the classroom through a multimodal lens has significant implications for learning. Thinking about learning as a process of design and choice (of representational modes) gives a new focus to the role of the learner. Design, diversity, and multiplicity emphasize the meaning-making practices and interpretative work of students. From this perspective the multimodal texts and artefacts that students make can be viewed as one kind of sign of learning, a material trace of the process of making-meaning. The interpretative work of students is reshaped through their engagement with a range of modes: image, animation, hypertext, and layered multimodal texts.

In such a view, students need to learn how to recognize what is salient in a complex multimodal text, how to read across the modal elements in a textbook or interactive whiteboard, how to move from the representation of a phenomenon in an animation to a static image or written paragraph, and how to navigate through the multiple paths of a text. These complex tasks—as against traditional taxonomies of print skills—are central to multimodal learning and development. Learning increasingly involves students in working across different sites of expression, negotiating and creating new flexible spaces for planning, thinking, hypothesizing, testing, designing, and realizing ideas (Jewitt, 2008).

New skills for reading, and for finding, authenticating, manipulating, linking, and recontextualizing information, are demanded in this multimodal symbol-saturated environment (Kress, 2003; Leander and Wells Rowe, 2006). Along with the choice of what mode to read, the structure of many digital texts opens up options about where to start reading a text—what reading path to take. This is a question that is intrinsically linked to how the relationship between mode and layout (itself an emergent mode) mediates the practices of reading and writing. The multimodal design of texts in the contemporary digital landscape often offers students different points of entry into a text and alternative possible paths through a text, highlighting the potential for readers to *remake* a text via their reading of it. The reader is involved in the task of finding and creating reading paths through the multimodal, multidirectional texts on the screen—an openness and fluidity of structure that seeps onto the page of printed books (Kress, 2003; Moss, 2003). Writing, image, and other modes combine to convey multiple meanings and encourage the reader to reject a single interpretation and to hold multiple possible readings of a text (Coles & Hall, 2001). In addition, new technologies make different kinds of cultural forms available, such as computer games and Web sites. This changes some aspects of the work of interpretation: New technologies offer the possibility of new spaces for publication and dissemination, and this has the potential to build new relationships between readers and writers in a manner that challenges and breaks down some of the traditional distinctions between them. These changes offer new possibilities for identity work and processes of reflection which are important for the future of teaching and learning.

Multimodal Text

WOLF-ANDREAS LIEBERT AND THOMAS METTEN

Multimodality has become one of the basic categories used in the analysis of texts. The development of digitalized print technologies, in particular, has led to the mass duplication of text designs. Multimodal texts can thus no longer be analyzed merely according to their linguistic considerations, that is, using monomodal methods, since a multimodal understanding of a text also includes an understanding of images, text design, typography, and the materiality of the text. This entry will attempt to give an overall view of the scope of such a multimodal text concept. The definition of text on which this entry is based excludes verbal utterances or discussions as well as cultural artifacts or occurrences such as film, theater, or hypermedia. This, however, does not apply to the concept of multimodality, which has become relevant in particular in the areas of interaction and speech research. Thus, Sigrid Norris (2004) developed a methodological framework for the purpose of analyzing multimodal interaction which has contributed to raising not only phenomena such as gaze, mimicry, and gesture but also corporality to the ranks of communication-relevant categories. The long-held view that such aspects were of little value in the field of linguistics has therefore now been discarded. This also has to be viewed as a decisive innovation in the multimodal approach: “then ‘language’ has to be seen in a new light: no longer as central and dominant, fully capable of expressing all meanings, but as one means among others for making meaning, each of them specific” (Kress, 2009, p. 79).

Texts as Semiotic Landscapes

Kress and Van Leeuwen’s studies of visual communication were at the forefront of the development of a multimodal definition of text. These authors put forward the fundamental hypothesis: “We believe that visual communication is coming to be less the domain of specialists, and more and more crucial in the domains of public communication” (Kress & Van Leeuwen, 1996, pp. 2–3). Multimodality therefore denotes, with regard to texts, the synthesis of various visual sign modalities. The *social semiotic* constitutes the basic theory of a multimodal understanding of text and works on the basis that signs have no set meaning in communicative processes, but merely create potential meaning that may be activated in different ways according to the context. Such a concept opens the way from the mere static concept of code to the dynamics of understanding. This is supported by the observations of Kress and Van Leeuwen, who wrote, “In our underpinning theory of social semiosis the idea of semiosis as work, as action, is central” (2001, p. 34).

The notion of mode is central to this multimodal approach. “Modes are semiotic resources which allow the simultaneous realization of discourse and types of (inter)action. Design then uses these resources, combining semiotic modes” (Kress & Van Leeuwen, 2001, p. 21). Here the notion of mode also serves as a means of creating a distinction between a multimodal approach and a static concept of code. However, what can be regarded as a mode within any given discourse is not always clearly definable.

Thus, Kress (2009, p. 79), for instance, classifies “writing, layout, music, gesture, speech, moving image, soundtrack and 3D objects” as modes. Similarly, color, smell, and taste—that is, the elements of sensory perception—are included (Kress & Van Leeuwen, 2001,

p. 28). Norris (2004) suggests that modes are always and only heuristic and that they have to be defined and redefined by the researcher depending upon the focus or depth of study, or both. Thus, for Norris, modes are not pre-existent. They are heuristic units that are useful for analytical purposes. This view differs from that of Kress and Van Leeuwen and does not lend itself to a development of grammars; but it also overlaps with Kress and Van Leeuwen's view, as the concept of "mode" allows the researcher to define the communicative functions (of actions).

The appropriateness of such different aspects as modes depends upon whether these aspects possess a communicative function. It is ultimately the aim of multimodal text analyses to develop grammars for the relevant modes as well as to define the relevant communicative function. When using such an approach in the development of mode-specific grammars a differentiation must be made between the perceptions of the participants. In terms of articulation and interpretation the modes act primarily in synthesis in the formation of meaning; that is, all the modes jointly construct the meaning of a text. Kress and Van Leeuwen have introduced the term "semiotic landscapes" in order to further illustrate the fact that communication only arises through an interaction of modes (e.g., 1996, pp. 33–40). A multimodal approach therefore defines texts as semiotic landscapes: "This is a multimodal text; the modes in use are *writing, image, number, color* (and *facial expression*). Social semiotics is able to say something about the *function* of each of the *modes* in this multimodal text; about the *relation* of these *modes* to each other; and about the main entities in this text" (Kress, 2009, p. 59). According to Stöckl (2006), a multimodal approach thus increases the status of the field of semiotics, since this is the only field extensive enough to provide an analysis of various nonverbal modes over and above the narrow scope of the area of text linguistics. Academic discussion in this area has also led to the extension of the field of text linguistics into text semiotics (see Eckkrammer & Held, 2006).

The Increasing Importance of Images

A crucial factor in the development of a multimodal approach to text analysis was the phenomenon of multimodality becoming more important than a monomodal, purely verbal configuration of texts (Kress & Van Leeuwen, 2001, pp. 3–4). Western cultures have been influenced by monomodal texts for a long time now: "In books of this kind [i.e., monomodal texts] it seems that the page has ceased to be a significant textual unit" (Kress & Van Leeuwen, 1996, p. 185). The increasing importance that has been attached to images in texts during the last few decades has therefore significantly contributed to the development of a multimodal perspective, and this also clearly shows the proximity of multimodal discourse to academic exchange in the field of visual studies. The discourse on the importance of images led to the so-called "iconic turn," whose chief exponents, William J. T. Mitchell (1992) and Gottfried Boehm (1994), almost simultaneously asserted the paradigmatic shift from language to images. The various traditions of multimodal research and research into visual studies are linked insofar as they are related to the phenomenon of the "image"; however, they are distinctly different with regard to how they interpret that image. While Kress and Van Leeuwen understand images as representations and fundamentally base their assumptions on a representational concept of characters, the "iconic turn" is more closely related to the "crisis of representation" that came up with poststructuralist concepts.

The understanding of visual communication and the relationship between text and images has thus received a great deal of attention in the field of multimodal text research. The classification of the interaction of verbal and visual modes seems to be something which is fundamental in literate societies. "Written texts and images have existed together

in many registers since the emergence of writing, and inscriptions are an integral feature of many sculpted objects and architectural artifacts" (Matthiessen, 2007, p. 29). Research into multimodality also often involves studies of the bimodality of texts, if these explore the question of how photographs, drawings, maps, graphs, or diagrams on the page of a book, newspaper, or magazine are coordinated with the written language. Therefore, from a semiotic perspective an "intersemiotic semantic relationship *between* the visual and verbal modes" emerges (Royce, 2007, p. 63).

Academic discussions about these relationships, however, are frequently marked by reservations which reveal an implicit devaluation of the image. This lack of recognition for the value of the image has been embedded in tradition since ancient times and can be seen as early as the 10th book of Plato's *Republic*. Thus Eckkrammer and Held (2006), for example, conceive forms of visual rhetoric as a reaction to purely emotional needs, and in so doing, devalue images in comparison to the more cognitive resource of language. The concept put forward by Eckkrammer and Held is often accompanied by the preconception that the meaning of images is indefinite, thereby necessitating the verbal definition of the content of those images. The concept of multimodality is directed against such a hierarchical classification of the relationship between texts and images, since this classification primarily results from the expression of cultural preferences (see Kress & Van Leeuwen, 1996, pp. 16–17). Images are thus not merely illustrations of a written text and can therefore not be regarded as redundant. In fact, the possible functions of images and the resulting relationships to text are far more complex. Thus text and images can, for instance, define each other reciprocally, extend each other's meaning, and function in or be integrated into a sequential relationship, as in a narration.

Research into such relationships in text now appears to be an established field. The prominence of the relationship between text and image has, however, led to the ignoring of transitions between the verbal and visual modes. Scripture can, however, be perceived in the form of language or images. Visibility implies iconicity. This is made clear in the phenomenon of text design.

Text Design and Composition

A multimodal understanding of texts has elevated the field of text design to one of the central categories within the analysis of texts, although for a long time monomodal artifacts even denied the existence of such an understanding. Kress and Van Leeuwen observed "that the layout of the densely printed page is still visual" (1996, p. 185). In this respect the irony of the "iconic turn" is the fact that texts have always been designed with visualization in mind, although it wasn't until after the "turn" that this concept was commonly realized within academic studies of texts. The ever-increasing possibilities in the area of digital design of printed matter in the last few years have led to the increased recognition of the visual dimension in printed texts. Thus, an upgrading of the significance of the iconicity of text took place from its former classification of being merely one element in the language system. Kress and Van Leeuwen focus in their analyses on the composition of meaning: "the visual component of a text is an independently organized and structured message—connected with the verbal text, but in no way dependent on it: and similarly the other way round" (1996, p. 17).

Bucher in particular has repeatedly introduced the expression "text design" into discussion of multimodal text understanding since the 1990s, in order to create a category for the purpose of describing design strategies in texts. While Kress and Van Leeuwen formulated the term "text design" as abstract and with reference to the combination of modes, Bucher in contrast placed greater emphasis on the communicative purpose of text design, thereby dissociating himself from a semiotic concept in a narrower sense (see

Bucher, 2007, p. 66; 1998). Text design includes aspects such as placement of an article, extent, and positioning on the page, as well as the setting of priorities and the use of images. These are, however, concrete aspects which Kress and Van Leeuwen also defined. In the transition from image to text design there are additional elements such as colored backgrounds, graphic design elements, tables, and the possibilities of diagrammatic text arrangement.

The communicative benefit of design becomes evident if one considers the example of a recipe in Figure 1. Recipes constitute a profoundly standardized text type, which as a rule consists of a list of ingredients for the relevant dish and a description of its preparation. Figure 1 displays a text which, with regard to its content, is designed as a script to instruct how to prepare a dish. However, by means of text design an artistic transition takes place, resulting in the exclusion of the separate list of ingredients. This is achieved by means of a rearrangement of the text on the page, so that the ingredients are displayed in the left-hand columns at the points at which they are needed for the preparation instructions in the right-hand column, as well as by typographical means—the use of italics for the ingredients. The design of the text in this case makes it possible to maintain the specific functions of a recipe, namely “display of the ingredients” and “instructions on preparation,” without having to designate these separately.

With the aid of this example a further dimension appears which is relevant to the multimodal approach to texts. The cooking recipe is not read in a linear fashion, but may be, according to necessity, viewed as a list of ingredients or instructions. Nonlinearity is thus shown to be a central feature of multimodal texts, and as such has been associated with the structure of hypertexts. In line with the multimodal perspective on texts it is evident that the assumption that the process of reception is linear is now outdated. (see Bucher, 1998).

Typographic Design and Typeface

Although composition and text design are a central feature in discourse in the area of multimodality, within this the area of typography has hitherto been barely broached. Sue Walker made the following observation in this regard: “The study of graphic language, concerned with the visual representation of thoughts and ideas, has largely been ignored by linguists, though there is growing interest in this area” (2001, p. xi). Stöckl also recognized the need for the establishment of such an approach, thus: “A multimodal perception of text and one emphasizing materiality demands graphic representation” (2004b, p. 7). Therefore it wasn’t until the last few years that the development of a perspective on the design of texts led to typographical aspects receiving increased attention from linguists. A multimodal perception of text opens up the possibility of comprehending the aesthetic value of typeface and relating this to aspects such as the thematic structure and function of any given text.

The choice of typographical style and aspects such as size and color then fall into the micro-realm of multimodal studies. In the meso-realm characters, words, and spacing are of importance, and in the macro-realm it is the arrangement of script blocks in relation to bodies of text. Text design in the macro-realm is therefore already an integral part of overall text design. In this regard, Figure 1 can also exemplify how “Using space and graphic marks to make it clear visually which bits of text relate to which is an important aspect of text articulation” (Walker, 2001, p. 11). Stöckl assigns several functions to the field of typographic design such as readability of the text, focus of the materiality, emphasis of specific statements, or the awakening of emotions (2004b, p. 40). The accentuation of these functions, however, continues to display an implicit degradation of typographical factors.

Marinierter Rehrücken		Badische Rehkeule	
4 Portionen		8 Portionen	
	Backofen auf 200 °C vorheizen.		Backofen auf 200 °C vorheizen.
1 kg Rehrücken	waschen, trocken tupfen und entlang dem Rückgrat an beiden Seiten so einschneiden, dass sich die Filets aufklappen lassen, aber noch an den Rippenenden mit den Rippen verbunden sind.	2 kg Rehkeule	häuten, waschen, trocken tupfen und den unteren Knochen auslösen.
1 Bund Petersilie	und	75 g Speck, fett	in Streifen schneiden, die Rehkeule damit spicken und mit würzen.
6 Zweige Thymian	waschen, Blättchen von den Stielen zupfen, mit	MAGGI Würzmischung 1	in Würfel schneiden, in die Fettpfanne geben und die Rehkeule darauflegen.
1 TL Rosmarin	und	75 g Speck, fett	und
4 Wacholderbeeren	hacken. Kräuter und Gewürze mit	1 Lorbeerblatt	zufügen. Ca. 90 Min. braten.
4 EL THOMY Sonne & Olive	mischen. Die Filets aufklappen, innen mit der Marinade einpinseln, zuklappen und von außen einpinseln. In Folie wickeln und mehrere Stunden marinieren.	5 Wacholderbeeren	Zwischendurch mit
	Fleisch auspacken, mit würzen und mit umwickeln. Durch das Rückgrat einen Metallstab schieben, damit es sich beim Braten nicht verbiegt. Im Backofen ca. 55 Min. garen. Fleisch warm stellen.	$\frac{1}{4}$ l Rotwein	und der Bratflüssigkeit begießen. Fleisch herausnehmen und warm stellen.
	Bratenfond mit vom Blech lösen, in einen Topf gießen, zum Kochen bringen und		Für die Soße: Bratflüssigkeit mit auf $\frac{1}{2}$ l ergänzen.
MAGGI Würzmischung 1		Wasser	
Küchengarn		1 Doppelpackung MAGGI Delikatess Rahmsoße zu Braten	einrühren. Unter Rühren aufkochen. unterrühren.
		2 EL Johannisbeergelee	
		1 Zwiebel	Für die Pilze: schälen, in kleine Würfel schneiden.
$\frac{1}{4}$ l Wasser		20 g Butter oder Margarine	In einem Topf heiß werden lassen und die Zwiebel darin andünsten.
1 Päckchen MAGGI Delikatess Soße zum Braten	einrühren, unter Rühren aufkochen und 1 Min. kochen. Mit	1 Dose (190 g) Pfifferlinge	abtropfen lassen, zugeben und ca. 5 Min. mitdünsten.
1 EL Aceto Balsamico	und	2 EL Crème fraîche Fondor	unterrühren. Mit
1 EL Rotwein	würzen und abschmecken. Rehrücken ablösen und in Stücke schneiden.	Pfeffer aus der Mühle	würzen und abschmecken.
		Petersilie, gebackt	Mit bestreut servieren.
1 Dose (425 ml) LIBBY'S Natursüß Birnen, halbe Frucht	abtropfen lassen. Den Rehrücken mit der Soße, den Birnen und		Rehkeule mit Pilzen und Soße auf Tellern anrichten.
4 TL Preiselbeeren	auf Tellern anrichten.		
		Brennwert je Portion:	2131 kJ (509 kcal)
		Nährwerte je Portion ca.:	E: 56 g; KH: 7 g; F: 27 g
	Brennwert je Portion: 2075 kJ (496 kcal)		
	Nährwerte je Portion ca.: E: 57 g; KH: 15 g; F: 23 g		

Figure 1 Example of a recipe (© “MAGGI Kochstudio—Das Kochbuch,” Mosaik Verlag)

The study of typographic design as a relevant dimension in the area of multimodal texts must, however, also take into consideration that such a view is subject to a perspective relative to culture. As an opposing model to typography one might cite the paradigm of calligraphy, which generally includes aspects of artistic writing. Therefore, not excluding

aesthetic aspects such as could be seen in calligraphy lends itself to the use of more general terms such as typographic design. Since the design and appeal of typeface are always dependent on varying materials, a multimodal perception or notion of texts understands these as tangible artifacts. Various materials such as paper, leather, stone, cloth, wax, wood, or clay, which are marked using colors or ink, may be used as a background. One can fundamentally differentiate according to whether this marking is done by hand or by machine. Pencil, fountain pen, stylus, or brush may be used as well as print technology and printing machines. In addition, the surface can be carved and/or printed by using a variety of methods. Kress and Van Leeuwen (1996, p. 231) observed, however, in this regard, "For the linguist, we think, surfaces and substances tend to be non-material until the very last, when an utterance is spoken or written, so that this last link in the chain of inscription . . . may seem less or even least significant." The theoretical basis for the examination of typographic design has hitherto not been greatly elaborated on and will require a greater level of research in the future.

The Disappearance of the Text Surface

The previous section demonstrated that on the basis of a multimodal notion, the surface of a text itself could in fact be deemed as relevant; however, it is still often subject to a degradation of its importance. It has hitherto not been possible for visual text phenomena to achieve a comprehensive upgrade of their importance. Text design and typography are still partially portrayed as a secondary semiotic system and as such are still regarded as subordinate to the language system's right of primacy (see Wehde, 2000; Stöckl, 2004a; Spitzmüller, 2006). Thus the discussion about their status has not yet reached its conclusion. However, if one looks back over the history of text design and typeface, one can recognize why such aspects were for the most part hitherto excluded.

The invention of the printing press with movable letters by Gutenberg is usually considered a turning point. If, however, one observes how the visual appearance of texts changes historically, one can see that the decisive development had begun 300 years before Gutenberg, during the 12th century. During this period the manuscript received a new character with the page image, chapter introduction, table of contents, and synopses. Gutenberg's invention didn't lead to a successive change in the appearance of text; rather he manufactured his letters based on the handwriting in the manuscripts. In total he used 299 different letters which resulted in typeface that was in no way inferior to that of a skillful scribe and was improved by hand if required (see Braun, 2006, pp. 230–2). Illich (1991, pp. 105–10) described the printing plate as the reification of a unified system of text design. Economic developments and the reduction of the printing devices to print just the letters of the alphabet led in the long term to a further simplification of the design of texts. Text, previously based on pen, ink, and paper, was thus changing to an abstract which was starting to detach itself from the physical reality of the page and could be regarded as independent from its tangible appearance.

During the course of the centuries the establishment of a unified and reduced print layout has led to the loss of the illustrativity of the written or printed page. The aesthetic expressive quality of a text was brought down to an absolute minimum (see Stetter, 2005a, p. 128). The principles of such a typographical culture are homogeneity, uniformity, and reproducibility (see McLuhan, 2003). This is the only way that the transition could be made from the visualization of a text to a mere language system and semantics which have dominated the monomodal perspective for a long time. If one considers that the constellation of language, script, and image harbors two interfaces, it becomes evident that linguistic research has paid most attention to the written language, while disregarding typeface.

Criticisms of Multimodal Perspectives on Text

Based on the historical developments that have taken place, the question has now arisen in current research of to what extent the development of a semiotic approach—as put forward by Kress and Van Leeuwen in their concept of multimodality—itself emerged in the face of the monomodal domination of linguistic understanding. Although much has been drawn from the field of semiotics in the context of multimodal research in order to enrich its orientation to language, a semiotic conception nevertheless reaches its limits ultimately, since the emergence of semiotics in a culture focused totally on written script is basically flawed. Thus a multimodal concept always acts on the assumption of the existence of varying modes, although these may themselves be the product of analysis. The fact that certain modes are considered to be significant and verbal modes are still a central focus, depending on their position, therefore demonstrates just how strongly Western cultures are influenced by the perception of written language.

The contribution of the concept of multimodality is, however, easier to understand if one considers it as distinct from the neighboring concepts of multisensuality and multimodality (see Table 1). The concept of multisensuality stems from the research conducted into linguistic cultures in the Middle Ages. In a culture which is oriented toward oral expression the communicative processes are tied to people and their senses. Perceptions in such cultures are differentiated according to whether they are visual, acoustic, or tactile. Textual artifacts thus have qualities such as colorfulness or a specific weight. The perception of text is multisensual insofar as the various aspects of a text interact in their reception.

This differs from a semiotic perspective which follows the concept of multimodality. Such a perspective classifies the various aspects in terms of the level of their differentiation and describes modes like text and images as grammaticalized phenomena. The formulation of such grammars forms the basis of the aim of multimodal research (see Kress & Van Leeuwen, 1996, p. 3). This issue is analytical and as such to be differentiated from the synthetic perception of the recipients. Multimodal research thus does well to isolate its own analytical interest from synthetic perception within the communicative process and not apply these equally to people. If with regard to aspects such as color a differentiated use can be identified, then this may be also described as a mode. This, however, does not assume any awareness of a mode on the part of the producer, since comprehension often simply proceeds casually. Thus a multimodal analysis must not presuppose the existence of modes, but may understand these as results or the product of the analysis.

The third perspective is oriented toward technologies and designated by the term multimodality, a differentiation which is also made within the area of multimodal discourse. “It follows that multimodality and multimedia are not quite the same thing. Radio . . . is multimodal in its affordances, because it involves speech, music and other sounds; but it is monomedial” (Kress & Van Leeuwen, 2001, p. 67). Media such as television and radio are therefore technical apparatuses which “outsource” the human senses: The camera “outsources” sight, the radio the sense of hearing, and so forth. Technologies can thus be

Table 1 Areas of reference

<i>Area of reference</i>	<i>Theoretical conception</i>	<i>Dimensions</i>
Perception/Senses	Multisensuality	Visual, acoustic, haptic, olfactory, tactile
Symbols/Modes	Multimodality	Script, image, gesture, facial expression
Technology/Media	Multimediality	Television, cinema, radio, newspaper, journal, book

conceptualized under the term of the ‘dispositive’ in the sense of Foucault (1978, p. 119). They create the conditions for the formation of meaning; that is, they form a framework or set a stage in which signs or symbols can be perceived, and they are also relevant for the production and distribution of meaning. In this respect they correspond to the level of perception. Such a classification thus enables the findings of multimodal research to be understood independently from the communicative process, while still using that communicative process as a basis.

Multimodality and Media Theory

In the course of the examination of nonverbal issues during the last few years, there has been repeated mention of the relevance of making communicative processes perceptible (see Fix, 2008), as a dimension of communication above all from a media theoretical perspective. Media theoretical positions, however, have hitherto played almost no role within the area of multimodal discourse, although there are future possibilities to expand the development of media theory, such as reflection on the role of script in the cultural development of Western societies. Script has been the subject of discussion in various schools of theory since the 1950s. In particular, the Toronto School of Communication in Canada and its main protagonists, namely Harald A. Innis, Marshall McLuhan, Eric A. Havelok, Ian Watt, and Jack Goody, examined the importance of script and its influence on the history of the Occident. McLuhan developed ideas on the design of magazines and advertisements as early as the 1930s. His *The Mechanical Bride* (1951) drew attention to aesthetics in advertisements and commented on these in order to encourage a detached view of and also to gain a real perspective on front pages and advertisements. The design of magazine titles, advertisements, and newspaper pages brought as early as 80 years ago the need for a different approach to texts. This was an issue which is today linked to a multimodal perspective on texts. Thus the works of McLuhan appear even now to be extremely current from a multimodal perspective. In addition, McLuhan (1962) also dealt with the development of text design and printing and termed these processes “the Gutenberg galaxy.” The expression doesn’t merely designate an era in the age of printing—which means being able to reproduce texts by means of specific print technologies.—but rather signifies a system of text design which resulted in a system of culture, and at the same time had an influence on the development of that culture. This is exactly the point Norris (e.g., 2004) makes.

In France it was above all poststructuralism that opened up a field of discussion in which script became relevant. Kress and Van Leeuwen refer to the French text theorist Roland Barthes and draw on his work for the concept of multimodality. The link between the concept of multimodality and the increasing dynamic of concepts of sign theory, however, may also be further developed from the philosophy of Jacques Derrida. Derrida’s work has to date not been acknowledged in the field of linguistics although he concerned himself intensively in his main early work *Grammatology* (1967) with Saussure’s linguistic conception. The conception of media philosophy put forward by Derrida emphasizes the relevance of materiality for the communicative process and is based on a notion of script in terms of labels. The approaches displayed here possibly open an expanded perspective for a multimodal comprehension of text, although as yet in media theory no substantiated notion of text exists. These theoretical traditions have thus far hardly been considered in discussions in the area of multimodal concepts because of the prominent position of semiotic concepts. It is quite possible, however, that these traditions could open up a new dimension and might even form the basis of a linguistic aesthetic sense, as demanded by Stetter (2005b).

Multimodal Text Analysis

KAY L. O'HALLORAN AND BRADLEY A. SMITH

Multimodal text analysis has become a crucial part of research, teaching, and practice for a wide range of academic and practical disciplines. A variety of techniques, theoretical frameworks, and methodologies have therefore evolved for such analysis. For linguists, in particular, concerned with accounting for the communication of meaning within texts, issues arising from the consideration of semiotic resources other than language, in interaction with each other and with language—such as gesture, gaze, proxemics, dress, visual and aural art, image–text relation and page layout, cinematographic and sound design, production resources, and so forth—have emerged in recent decades as important challenges. Meanwhile, the emergence of multimodal studies as a distinct area of study in linguistics has also revealed a range of issues specifically relevant to the multimodal text analyst.

Multimodal analysis includes the analysis of communication in all its forms, but is particularly concerned with texts which contain the interaction and integration of two or more semiotic resources—or “modes” of communication—in order to achieve the communicative functions of the text. Such resources include aspects of speech such as intonation and other vocal characteristics, the semiotic action of other bodily resources such as gesture (face, hand, and body), and proxemics, as well as products of human technology such as carving, painting, writing, architecture, image and sound recording, and, in more contemporary times, interactive computing resources (digital media hardwares and softwares). Different semiotic resources bring with them their own affordances and constraints, both individually and in combination, as well as analytical challenges in terms of the natures of the media, the detail and scope of analysis, and the complexities arising from the integration of semiotic resources across media.

While it has long been understood that human meaning in the round involves more than simply the (written) language studied by the early linguists (see Saussure's observations on the need for a semiological science [1916/1974, p. 16] “that studies the life of signs within society”), practical and theoretical challenges have meant that it is only in recent decades that a distinct field of multimodal studies has begun to emerge, and many issues remain unresolved within this field, particularly with respect to text analysis. Halliday (1985) has observed that it was not until the wide availability of sound-recording technology (in particular, tape) that widespread empirical study of authentic natural spoken discourse began, with profound consequences during the 1960s and 1970s for linguistic theory and methodology. Yet studies of speech, as well as other modalities, have long remained tied to the analysis of transcriptions rather than a direct, ongoing engagement with the source text, bringing issues of transcription to the fore that are relevant to multimodal text analysis (see Ochs, 1979, for a discussion). The reasons for this constraint are clear: in the first instance, the difficulties of accessing and annotating dynamic audiovisual media such as sound and film are manifest, and modern interactive hypermedia have added further difficulties (e.g., Lemke, 2002). Second, and as a result, without such access and annotation capabilities a close, repeated, analytical attention to the source text has been difficult, meaning either that theoretical development has tended to occur without extensive grounding in empirical analysis, or that when such grounding is present—where multimodal analysts derive general principles from the close, sustained study of multimodal

2 MULTIMODAL TEXT ANALYSIS

phenomena within actual text—the texts tend to be static (visual) media or such as can readily be examined and reproduced on the printed page. If the texts analyzed are dynamic, the issues of transcription, multimodal analysis, and reproduction for publication are palpable, particularly in print-based approaches which offer limited resources for multimodal text analysis (e.g., Baldry & Thibault, 2006; O'Halloran, Tan, Smith, & Podlasov, 2010; O'Halloran, 2011a).

Two major strategies have thus emerged for dealing with these challenges, constituting two of the major approaches by which multimodal text analyses can be characterized: one is to explore theory, using text analysis as both test and illustration of the discussion of general principles; and the other is to explore actual texts, working from such analyses toward generalizations. The first approach does not assume and indeed problematizes theory, and much of the work is involved with comparing and integrating knowledge and practice from often disparate theoretical traditions. Multimodal studies suits such an approach, when one considers the wide range of disciplinary and theoretical traditions to which multimodality is relevant. In this approach, theoretical generalization is often applied to analyses across several different texts and text types, in order to derive, test, and illustrate general principles. The second approach is to pay very close attention to and work from actual specific texts, where the focus is upon the text, building up detailed description, often as a form of running annotation (particularly if the text is dynamic), and usually adapting and applying an established theoretical and descriptive framework, but deriving descriptive generalizations out of such text analysis and modifying theory as a result. In this approach, analytical detail is paramount, and again, the challenges of access, transcription, analysis, and reproduction in publication are all too apparent.

It is interesting to note that two pioneering works in multimodal text analysis, roughly contemporaneous, can be characterized with respect to these generalizations. The first derives from, among other influences, a synthesis of social semiotics, European semiotics, and critical discourse analysis traditions. The exemplar work is Kress and van Leeuwen (1996), where powerful theoretical generalizations from these different schools of thought are applied, calibrated, and synthesized via consideration of a diverse range of texts. The multimodal text analysis appears as both a reference and an illustration for the discussion at hand; but it is the theoretical discussion which drives the analysis and text description: generalizations are paramount, while the analysis is usually conducted and presented discursively. Thus, Kress and van Leeuwen (1996) begin a general discussion about the title of the book, highlighting the difference between a “grammatical” and a “lexical” approach to the semiotics of visual design from the perspective of social semiotic theory; stressing the importance of the distinction between formal and functional theories; and highlighting the relation of specific multimodal features, structures, and systems to more general social (particularly power) structures and (ideological) forces:

The dominant visual language is now controlled by the global cultural/technological empires of the mass media, which disseminate the examples set by exemplary designers, and through the spread of image banks and computer imaging technology, exert a “normalizing” rather than explicitly “normative” influence on visual communication across the world. Much as it is the primary aim of this book to describe the current state of the “grammar of visual design,” we will also discuss the broad historical, social and cultural conditions that make and remake the visual “language.” (Kress & van Leeuwen, 1996, pp. 4–5)

The second approach was pioneered and is best represented by the work of Michael O'Toole (2010 [1994]). O'Toole (1995, p. 159) provides an “adaptation of Systemic-Functional grammar” as “at least some shared (or sharable) terminology and assumptions,” stating: “My

thesis is quite simple: Michael Halliday's Systemic-Functional linguistics offers a powerful and flexible model for the study of other semiotic modes besides natural language, and its universality may be of particular value in evolving new discourses about art." Here, as in later studies O'Toole's work has a characteristically close analytical orientation to specific texts, explicitly working, in the first instance, analytically from the text itself rather than from perspectives outside of the text, such as historical, biographical, or mythological interpretations. O'Toole (1995, p. 159) prophetically argues that "a proper semiotics will only grow out of a large body of analysis, description, interpretation and theory by people with a range of orientations."

Thus O'Toole advocates an approach that provides tools, adapted from linguistic theory and description, for working from specific texts—(and the title is significant in this regard), while Kress and van Leeuwen (1996) develop an approach that explores generalizations out of the study of different types of theory and text, and from the integration of theories to apply to texts in general, including, importantly, extratextual perspectives (e.g., related to the analysis of ideology, historical power structures, and so forth). However, O'Toole (1994) also later works toward social semiotic generalizations, drawing upon a wider range of theoretical traditions; and Kress and van Leeuwen include a wealth of useful analysis derived from the application of a coherent theoretical framework: The difference, that is, is one of approach and aim.

In both these foundation works in multimodal studies, although reference is made to the study of dynamic audiovisual text, there is a preponderance of static visual art as data. Earlier multimodal text analysts also either tend toward an analytical focus on static visual text (e.g. Barthes' famous 1957/1972 *Paris Match* analysis) or, when confronting dynamic (audio, visual) texts, are compelled to rely on discursive description or generalization rather than on the presentation of detailed empirical analysis as the foundation for discussion. In practical terms the analysis of static art is relatively feasible even within the constraints of the printed page, while the multimodal analysis of other media, as discussed earlier, points clearly to the difficulties of representing on the printed page the mass and complexity of detail involved in multimodal analysis, and of capturing the dynamism and dimensionality of audiovisual film, hypermedial navigation, and so forth (e.g., Lemke, 2002; Baldry & Thibault, 2006).

Thus, while the difficulties of multimodal text analysis are apparent in most works which explore this field, there has nevertheless been built up over time a corpus of detailed multimodal analysis which has provided the means for testing, exploring, and illustrating ideas about how multimodal communication works. It is important to recognize in this respect that while it is only in recent decades that extensive multimodal text analysis has heralded the emergence of a distinct field of multimodal studies, in fact the study of multimodal communication and artifacts can of course be found in the long lineage of works within anthropology, archaeology, art criticism and history (painting, sculpture, music, theatre, opera, film, and so forth), computer science, engineering, psychology, and all fields of research engaged with human or nonhuman communication. The related practical disciplines, such as the various forms of art, also provide ample material for multimodal text analysts to draw upon. In addition, in recent decades the rapid increase in sophistication and availability of technological (particularly computational) resources and techniques for analysis of multimodal text has no doubt driven the rapid increase in multimodal analyses appearing within a range of disciplines, vastly improving, as technology did for the study of speech earlier, our access to and understanding of multimodal text using, for example, multimodal annotation software (e.g., Praat, ELAN, MacVissta; see Rohlfing et al., 2006). The ongoing development of interactive digital techniques, along with the increasingly collaborative nature of research in the 21st century, points to a period of further growth in coming years within this field.

It is clear that both the empiricism of detailed, exhaustive text analysis (coping with the challenges this raises) and the ongoing problematization and exploration of theoretical generalization and abstraction are needed for the development of resources for and practice of multimodal text analysis. In addition, multimodal text analysis requires the integration of both low- and high-level analyses: As with early studies of intonation, the study of multimodality has been centrally concerned with the material plane, the organization of the physical (including technologically driven) phenomena by which meaning is created, in their relation to higher-level grammatical and semantic organizations such as abstract, semiotic systems and structures. How to relate what Hjelmslev (1961) called the content and expression planes has been a central challenge for multimodal analysts, and this challenge has become more acute as sophisticated instrumental analysis—particularly computational automated techniques for feature extraction—make possible the analysis of primarily low-level features within large corpora of multimodal text. The availability of such techniques is both a great opportunity and a difficulty for scholars of multimodal communication: One major challenge is to trace and make explicit the path from such automatically detected features to the sociocultural patterns significant to multimodal analysis of text, in ways that draw upon the respective riches of computational and semiotic sciences, as well as the knowledge and practices of other disciplines such as mathematics, physics, psychology, ethnography, and so on. The immediate demands of multimodal text analysis in fact become the site for the exploration of synergies between disciplinary and theoretical traditions, as we seek to understand actual texts through the kaleidoscope of the multitude of relevant perspectives.

The variety of work and approaches within this range of somewhat disparate fields of science and humanities research constitutes both a rich resource and a challenge for the multimodal analyst. One must sort through the complementarities, inconsistencies, and redundancies of the different approaches and perspectives, working out which types of analysis suit which research project—some approaches being more appropriate to certain tasks than others. This has been a key issue with respect, in particular, to the adaptation and application of linguistic theory and description, which has been an important influence upon multimodal studies. Multimodal analysis must of course include analysis of language where relevant; but in the analysis of semiotic resources other than language, whether involved in intersemiotic relations with language or not within a particular text, the question of how much of linguistics can be adapted for the analysis is still an open one (Machin, 2009). It is important to note in this respect the difference between the application of general theoretical principles and the adaptation of a specific description (of, for example, language or languages): As O'Toole has shown, it is the former (social semiotic theory) that drives the development of descriptions of semiotic resources other than language, while the latter (linguistic descriptions) can nevertheless provide useful materials, if appropriately adapted, for such descriptions. But the same question can be applied to work within all relevant disciplines: Determining the affordances and constraints of theories, descriptions, and methodology adapted and applied from existing disciplines and traditions is a crucial challenge for multimodal text analysts.

Other issues remain for the multimodal text analyst. For example, the issue of corpus constraint continues to challenge multimodal text analysts: Gathering multimodal corpora has become increasingly difficult, not least because of ethical concerns which become acute when audiovisual recording of naturally occurring discourse is available. There are also difficulties in terms of data collection (such as the recording process itself, often involving technical expertise not always at hand for multimodal analysts), and the dynamism and hypertextuality of contemporary interactive digital media have compounded this issue. The issues of detail, scope, and complexity also continue to bedevil multimodal analysts, an issue raised as early as the 1960 study of the psychiatric interview *The First Five Minutes*

(Pittenger, Hockett, & Danehy, 1960), but becoming increasingly evident with the availability of sophisticated interactive digital software applications which provide platforms for an ever-more minute analysis of multimodal phenomena. As Halliday and Greaves (2008) point out, the human analyst can never be replaced by computer-based or other technology-based approaches, but such resources increase the power of our analytical reach (for example, via low-level feature extraction, mathematical processing, visualization techniques), presenting richer but more complex and detailed phenomena to analyze. A key issue for 21st-century multimodal text analysis is to find principled ways of sorting through and making sense of such complexity and detail.

The applications and value of multimodal text analysis are immense. Multimodal communication is central to human existence, and yet such is the nature of multimodality—the joining of abstraction and material in semiosis—that this is an area of the natural world that still remains relatively underexplored, and not well understood, compared with the material plane. Jewitt (2006) and others (e.g. Lemke, 1998; Unsworth, 2008; O'Halloran, 2011b) have shown how important an understanding of multimodality is to the study of classroom discourse and education; the integration of knowledge and techniques from multimodal semiotics science promises new approaches to the development and study of computational science; and multimodal text analysis has been shown to be crucial to a consideration of a wide range of fields (e.g., Jewitt 2009). The proliferation in forms of contemporary interactive digital media and the ubiquity of their use puts demands upon scholars of human communication to keep up with wider sociocultural developments. What is required at this stage in the development of multimodal studies as a field is the sort of empiricism of extensive text analysis that revolutionized the study of language during the 1960s and 1970s. To do this will inevitably require that analysts of multimodality learn to use (particularly contemporary digital) multimodal resources and techniques in order to appropriately deal with the natures of such media: to paraphrase Firth (1957), to turn multimodal language back on itself.

Multimodality and Comic Books

MARÍA JESÚS PINAR SANZ

In recent decades there has been an increasing interest in the way several semiotic modes relate to each other and how their combination within a sociocultural domain results in a semiotic product or event (Kress & van Leeuwen, 2006; Kress, 2010). Text and images are increasingly coming together, creating multimodal texts. The relation between the verbal and the visual has been amply studied in different fields such as picture books (Nikolajeva & Scott, 2001; Moya & Pinar, 2008, 2009), mathematical discourse (O'Halloran, 1999), scientific texts (Lemke, 1998), political cartoons and billboards (El Refaie, 2003, 2009; Pinar, 2008), or simply signs (Kress, 2010), among others. Most of these studies follow a systemic-functional and/or social semiotics theoretical framework (Halliday, 1994; Kress 2010). Increasingly, multimodality is also studied and theorized within the cognitive linguistics paradigm. This entry offers an overview of the interplay of multiple modes of meaning-making in comics, focusing mainly on linguistics-inspired work. Unfortunately, it has to forgo much relevant work originating in other fields, such as the comics scholarship.

Work in the field of comic books—including graphic novels, web comics (Zanfei, 2008; Goggin & Hassler-Forest, 2010), and autobiographical comics (El Refaie, 2011)—is becoming increasingly popular. They can be considered as a genuine multimodal genre whose meaning is constructed out of combinations of different modes, and where each mode has a specific task and function. Kress (2010, p. 79) states that a mode “is a socially shaped and culturally given semiotic resource for making meaning.” He includes a number of modes used in representation and communication: image, writing, layout, music, gesture, speech, moving image, soundtrack, and three-dimensional objects. Forceville (2009, p. 23) also includes smells, tastes, and touch. According to Kress (2010) these modes form modal ensembles “based on designs or selections and arrangements of resources for making a specific message about a particular issue for a particular audience” (Kress, 2010, p. 28). In comics, most of these modes are used for meaning-making, either in monomodal or multimodal combination, in order to convey a sequential narrative and to produce an aesthetic response in the viewer (Eisner, 1985; McCloud, 1993, p. 9).

Multimodality in comic books has been the focus of interest of several researchers, mainly from an interdisciplinary approach. McCloud (1993) is a pioneer in this field. He introduced several terms to explain the relationship between the verbal and the visual in comic books, ranging from “word-specific” or “image-specific” (one mode carries the meaning and the other adds nonessential detail) to “interdependent,” where both modes together produce meanings that neither could convey alone (McCloud, 1993: 153–63; El Refaie, 2009). This seems to be the most popular word/image combination in comics.

Other authors within the field of multimodality and comic books are Baldry and Thibault (2006), who include a multimodal transcription of a comic strip and an analysis of two single panel cartoons; Forceville (2005) and Eerden (2009), who study the visual representations of anger in Asterix; Shinohara and Matsunaka (2009), who focus their attention on pictorial metaphors of emotion in Japanese comics; Kaindl (2004), who analyzes multimodal aspects in the translation of humor in comics; Yannicopoulou (2004), who researches visual literacy in preschoolers' reading comics, and Forceville (2011, p. 875), who presents a model to research pictorial runes “by inventorying and categorizing all specimens occurring in

2 MULTIMODALITY AND COMIC BOOKS

a single Tintin album"; and Cohn (2007), who studies the varying levels of representation in visual language in comparison to the structural makeup of verbal language in order to define visual lexical items in comics. Cohn (2010) also studies metonymy, conceptual metaphors, and blending in an advertising campaign. All these authors agree with the fact that a model of analysis for comic books construed on the basis of language alone "may ignore or downplay information that is more prominent or more readily available in other sign systems" (Forceville, 2005: 71).

The above text has introduced the term multimodality and most specifically multimodality in comic books, the modes used, and the different approaches to comics from different experts in the area; the main techniques and conventions will now be described. Comics avoid the use of extended texts. This allows comics to be extremely inventive in developing techniques to denote emotional status or changes, or emotions in general, such as surprise, disappointment, despair, anger, or happiness. These techniques become conventions used in order to convey narration and speech and evoke emotional or sensuous responses. In most cases, the conventions are visual or pictorial devices which may be realistic or non-realistic, or, using McCloud's words (1993, pp. 128–9), represent the visible or the invisible. The conventions used to convey narration and speech include panels, motion lines, and gutters. Panels are the images usually laid out within borders. These borders or edges are called frames and are normally rectangular in shape. This shape, though, can be altered to convey information to the reader and it becomes a pictorial rune. A cloud-shaped panel, for example, can indicate a flashback or a dream sequence, while one with a jagged edge can be used to convey anger or shock, as in balloons. Panels constitute the macrostructural level within the panels (Kaindl, 2004, p. 183) and are the abstract lines that appear behind a moving object or person to make them look as if they are moving quickly. Line length may be said to vary proportionately to the rate of speed of the object moving (McCloud, 1993, pp. 110–11). Finally, the gutter is the space between borders and is identified by McCloud as one of the most important narrative tools in comics, as it encompasses everything that happens *between* what happens in the panels. In gutters, "human imagination takes two separate images and transforms them into a single idea" (McCloud, 1993, p. 66).

Kennedy (1982) introduced the term "runes" for nonrealistic visual or pictorial metaphors: "the kind of non-iconic signs used profusely in comics and cartoons to indicate speed, pain, surprise, happiness, anger and many other phenomena by means of straight or squiggly lines, stars, bubbles, etc. surrounding characters or moving objects" (Forceville, 2009, p. 23). Related to pictorial runes is onomatopoeia, a convention central in (mainstream) comics which represents sounds. One example of onomatopoeia is the single letter "z" as the sound of a snore or of a person or animal sleeping, "bzzz" for the sound of a flying insect or "aaagh" to express pain. The multimodal nature of comic books is also shown in balloons, "one of the most defining visual conventions of the comics medium" (Forceville, Veale, & Feyaerts, 2010, p. 56), which are a visual means of conveying words and emotions in comic books and comic strips. Visual variations in balloons are many. Forceville et al. present a "provisional blueprint of the visual variables governing balloon information" (2010, p. 56). Speech and thought balloons are probably the most widely used. The first typically have pointed tails directed to the speaking character while the latter are generally cloud-shaped or circular with an increasingly smaller chain of circles directed at the character in thought. Another type is broadcast balloons, which may have a jagged tail like the conventional drawing of a lightning flash and either a squared-off or jagged outline. Letters are sometimes italicized without necessarily being bold. Broadcast balloons indicate that the speaker is communicating through an electronic device, such as radio or television or is robotic (McCloud, 1993).

Speech balloons indicate spoken words, while thought balloons indicate a character's thoughts. They also contain symbols which are constantly being used to cover the non-verbal (McCloud, 1993, p. 134) and also to depict character's emotions much more efficiently than any possible sentences. This is the case of the use of a single punctuation mark to depict a character's emotion. A speech balloon with a single big question mark (?) denotes confusion or ignorance. An exclamation mark (!) indicates surprise or terror. Singing characters usually have musical notes drawn into their word balloons. A stormy cloud with a rough lightning flash sticking out of it, either in a balloon or just floating above the character's head as a modified "cloudy" thought balloon, depicts anger, not always verbally expressed, and little daggers are physically present when someone is looking daggers at somebody else (Zanfei, 2007). Light bulbs are sometimes used when the character comes up with an idea or solution to a problem and, following Zanfei (2007, p. 398), a shrugging of the shoulders can be considered as a relevant answer. Profanity is normally replaced with a string of nonsense symbols (&%\$@*€#), sometimes called grawlixes. According to Yannicopoulou (2004, p. 172), these visual metaphors of disguised anger have proved so popular that they have gained the status of a frozen metaphor.

There are different types and shapes of speech balloons used to help convey the tone of the dialogue to the reader in conjunction with differences in size or depth of color of the printed words (Forceville et al., 2010, p. 63), which correspond to differences in volume of the reader's inner voice (Yannicopoulou, 2004). Writing uses graphic means—bold type, size, spacing—to achieve semiotic effects which are only in some respects similar to those produced by sound in speech (Kress, 2010, p. 80; Zanfei, 2007, p. 398). If specific words in a passage are written in bigger, bolder, or capital letters, it calls for a louder voice; if the letters are smaller, readers have to lower their voices. For example, angry speech or shouting may be indicated by text inside jagged-edged speech bubbles. Their lettering is usually larger or bolder than usual. Normal conversation is usually indicated by text inside simple circular or square-shaped speech balloons. Whispers tend to be represented by balloons made up of broken lines, smaller font, or gray lettering, which indicates the tone is softer, as most speech is printed in black. There are other devices to visually suggest an increase in volume. Following Yannicopoulou (2004), when words break the borders of the speech balloons and penetrate their adjacent frames, the reader-viewer can "see" yelling, shouting, and uproar. The result is a multimodal metaphor: "the eye can hear" (Martinidis, 1991). In addition, other shapes are used to convey feelings, such as icicle balloons, which have jagged "icicles" on the lower edge and indicate that the speaker is "ice cold" towards someone or something. Similarly, the speech balloons for monsters may have an outline that suggests dripping blood or slime. Colored balloons may convey the emotion that goes with the speech, such as red for anger or green for envy.

Finally, captions are other devices generally reserved for narration rather than dialogue and take the form of squares of text attached above or below the panel. Captions can be used in place of thought balloons, can be in the first, second, or third person, and can either be assigned to an independent narrator or one of the comic's characters. Like word balloons they need not be of uniform shape, size, design, or color (indeed, some modern comics use different colors to assign different textual captions to different characters).

The ideas expressed in the previous paragraphs confirm the initial claim that comics are genuine and complex multimodal texts. The repertoire of means of expression in comics include verbal, pictorial, and typographic signs which combine in a monosensory medium (the comic, which relies on only one of the senses—the eyes—to convey a world of experience) in order to transmit multimodal meanings. Following Norris (2004), these sign systems or modes should be considered as "embodied modes," implying that they may have a superordinate or equal value with respect to language. In fact, as Zanfei (2008, p. 60) points out, language and images are independently organized and structured messages

whose codeployment and interplay make the whole meaning of the composition of the page.

One of the general principles of multimodality in comics drawn from the data above is that visual elements, for example, can convey aural stimuli and readers/viewers are forced to “hear” with their eyes. As mentioned above, the form of writing suggests how to read the text. Bold type in writing and loudness in speech are both signifiers of intensity (Kress, 2010, p. 80) and are one means of realizing meanings of “emphasis.” Therefore, differences in size or depth of color of the printed words correspond to differences in volume, and differences in shapes may express a variety of emotions in combination with the verbal part. The implications of multimodality and comic books in applied linguistics are daunting. Visual elements contribute to the construction of meaning and it implies that just by looking at the text the reader-viewer gets a large amount of information, such as the emotional state of the main character if he or she is whispering or shouting (Forceville, 2005) or if the text is a dialogue or first person narration (Yannicopoulou, 2004).

Multimodality and Culture

PIA LANE

The world we live in and our research have become increasingly multimodal and culturally complex. Multimodality as an object of research and as a research methodology is relatively new in applied linguistics, whereas culture has been a central concept for a long period. This entry provides a brief overview of the term “culture” as it has been understood within the field of cultural and social anthropology by highlighting the parallel developments within linguistic and anthropological research during the past decades. Many researchers now see concepts such as “culture” and “language” not as static entities, but rather as fluid and dynamic, created and shaped through human action. These processes have been spurred by technological developments, offering both new modes of communication and new tools of analysis.

What Is Culture?

Academic disciplines have concepts which are essential to their theory and method, and as a consequence such terms become constitutive for the discipline. Culture is such a key concept, and it has been central particularly to the field of anthropology, much as linguistics has claimed ownership of “language.”

The term “culture” has been discussed for decades, which is not surprising since the object of study for anthropological research is cultural variation. The way culture has been understood has varied across time and research traditions. The etymological root is Latin *colere*, “cultivate” (Hylland Eriksen, 2010). Within cultural anthropology “culture” is used to refer to “knowledge about those aspects of humanity which are not natural, but which are related to that which are acquired” (Hylland Eriksen, 2010, p. 3). There is a tension between the universal and the particular: all human beings are similar in the sense that we have culture, but this is also what makes us differ from one another. The investigation of this double nature of culture has been central to anthropology ever since its inception, and culture has been a key concept, both defining and dividing the field of anthropology. When it comes to the tension between the universal and the particular, there is a striking resemblance to discussions about language within various disciplines of linguistics: is language primarily an individual or a social object?

Our concern here is how the understanding of culture may shed light on applied linguistics in general and multimodality in particular. Linguists take for granted that culture is important, and the term is frequently used but rarely defined. In spite of not defining culture, literature within anthropology, applied linguistics, and sociolinguistics frequently uses and builds analyses on this term. Therefore, a brief outline of how culture has been understood within social and cultural anthropology is a useful starting point.

Culture: A Defining Concept for Anthropology

During the 19th century several academic disciplines, influenced by Darwin’s theories, were characterized by a focus on evolution. The primary aim of linguistics was to reconstruct former versions of languages in order to postulate a common source. During the

2 MULTIMODALITY AND CULTURE

same period anthropology also underscored that human culture underwent qualitative change and evolutionism offered tools for analyzing and describing this change. Barnard and Spencer (1996) point out that this period was characterized by a focus on culture as an entity that evolved and could be possessed and acquired by societies to varying degrees. A different viewpoint was offered by the American anthropologist Boas, who, inspired by Herder and the German tradition and by his fieldwork among Native Americans, used the plural form of culture: “cultures.” This can be seen as the inception of modern anthropology, situating culture in the tension between the individual and the particular referred.

Other similarities in the theoretical underpinnings of anthropology and linguistics can be identified, such as the striking similarity in the focus on underlying structure brought forward by Lévi-Strauss (1971) and Chomsky (1965), respectively. The idea is that the human drive to classify and create structure is driven by the underlying binary nature of the human mind and a search for universal patterns (Keesing, 1974). Chomsky’s postulate that all children were born with the same abstract grammatical structure had a profound impact not only on linguistics, but also on psychology and other disciplines. Language came to be seen as innate, biologically grounded, and separate from other cognitive processes.

Academic fields often undergo similar theoretical paradigms. Today, both linguistics and anthropology have been shaped by poststructuralist theories, emphasizing pluralism and hybridity, human agents as co-constructors of language and culture, and a shift of focus from the study of Others to investigating relationships and transnational flows. The term “culture” still is frequently used, but contemporary introductory books to anthropology typically discuss the history of the term, rather than providing definitions. However, when definitions are given, they tend to highlight the interactional, inclusive, relativistic aspects of culture. Bodley (1997, p. 10) emphasizes culture as learned social behavior and offers the following definition:

Culture involves at least three components: what people think, what they do, and the material products they produce. Thus, mental processes, beliefs, knowledge, and values are parts of culture.—The shared aspect of culture means that it is a social phenomenon; idiosyncratic behavior is not cultural. Culture is learned, not biologically inherited, and involves arbitrarily assigned, symbolic meanings.

This definition emphasizes culture as something acquired and contextualized, in line with the definition provided by Hylland Eriksen: “a sensible concept of culture must depict culture both as an aspect of concrete, ongoing interaction and as the meaning-context for the very same interaction” (1991, p. 127).

Contemporary anthropology’s discussions of culture clearly are situated in a poststructuralist context, which also is the case for the following definition from applied linguistics: “Culture is located then not in accumulated bodies of static knowledge, but in the daily interactions occurring between individuals in particular sociocultural contexts at particular moments of time” (Hall, 2008, p. 50). To summarize: currently culture is understood, similar to the way language is perceived by many linguists, as a combination of stable and co-constructed, fluid and contextualized patterns of behavior; both as something humans have and something we do.

Culture, Language, and Multimodality

Anthropological research has always been concerned with multimodality, though the term “multimodal” has not been used until recently. This concern has been manifested both by its object of study (social behavior, traditions, material culture, language, etc.) and by the

choice of methods (participant observation, written field notes, photography, ethnographic film, etc.). The history of linguistics, however, differs. The object of study for linguistics is language and before the advent of recording possibilities, linguists relied on written transcripts of spoken language. Linguistics discussed whether language is best understood as a sociocultural object or a biological object. This, combined with smaller range of research tools than was the case for anthropology, led to linguistic research in general being monomodal. Though the emphasis was placed on spoken language, linguists worked with written elicited forms or written transcripts. During the structuralist period and, later, from the Chomskyan revolution, culture was not allocated room in the investigation of language because language was seen as a self-contained system.

The 1970s brought about a profound change, both in the view of language as an object of study, and also in language as a source of data. Sociolinguists and applied linguists turned to contextualized analyses of language, and new recording technologies made it possible to analyze audio recordings of spoken language as well as transcripts of these recordings, facilitated by sophisticated transcription systems developed within ethnomethodology and conversation analysis, research areas originating in sociology. In combination with these new technological means, focus shifted to the contextualized use of language, seeing language as shaped by societal and cultural factors. Though not necessarily using the term “multimodality,” a wide range of linguists began analyzing more than language in the traditional sense. Within variationist sociolinguistics Eckert (1989) shifted the focus from dialect to style, analyzing not only phonological variation in youth language, but the interrelation between language and other semiotic resources as means for identity construction and group membership. Schiffrin (2006) also investigated the relationship between language and context, focusing on how language is part of (and contributes to) text and context. Interactional sociolinguistics has, since Gumperz’s (1992) groundbreaking work, had a focus on how meaning is contextually created and how we use different linguistic resources like choice of lexemes, intonation, stress, and information structure to convey meaning, pointing to different frames of reference. Depending on our cultural baggage we use language in systematically different ways, but the relationship between language and culture is not static. Duranti and Goodwin (1992) draw our attention to the mutually reflexive relationship between talk and context, seeing language as a contextualized phenomenon, both shaping and being shaped by context. Likewise, applied linguistics underwent a similar process, moving away from a mentalist view of language seen as an object in the mind to the 1990s, when “advances in cognitive linguistics, linguistic anthropology, and the growing importance given to culture in language education brought a renewed interest in the relation of language, thought, and culture in applied linguistics” (Kramsch, 2004, p. 235).

These intellectual developments from the 1970s onward challenged the notion of language as an autonomous entity, and, fueled by technological advances both in text production and in tools for data analysis, language came to be seen as a part of a larger social system. Thus, the links between language and culture that had been severed during the preceding century were reunited. As a consequence, researchers turned to analyzing different modes of language and their cultural context.

Technology and Culture

Communication has always been multimodal because we never have relied on oral aspects of language only. Language, gesture, pose, and so forth have all contributed to the production and understanding of a message. Likewise, text production is shaped by its cultural context. Medieval texts were ornamental, and the materiality of texts contributed to their

meaning (Caie, 2008). The advent of the printing press, and later the typewriter, standardized text production, and the written text came to be, at least implicitly, understood as language *per se*. Technologies always entail some degree of standardization, involving codification, abstraction, and changing the conditions and scope for human agency. These technological developments, intertwined with the notion of language as a monomodal abstract entity, underpinned linguistic research to a large degree until the 1970s. The paradigm shift described in the previous section was facilitated by technological developments for data gathering and analysis. These processes have been furthered by recent technological developments as the production of all forms of written, spoken, and visual texts has become more complex through the use of different modes; all types of texts are more widely disseminated due to technological means, and we have developed more sophisticated tools and theories for the analyses of multimodal data. Therefore, it is not surprising that a wealth of multimodal research has emerged. For much of this research, "culture" is a central term, though, as is the case for most writings within linguistics and anthropology, the term is frequently used but not always defined. Often, other terms and concepts are used in tandem or interchangeably with "culture," such as "context," "social practice," "semiotic systems," as in the following definitions: "The semiotic landscape consists of objects and events which together constitute the phenomenon we call culture" (O'Halloran, 2009, p. 98); or Jones's (2005, p. 143) rejection of essentialist notions of culture, "preferring instead to speak of the nexus or intersection of practices (Scollon, 2001) upon which people build individual and group identity."

Multimodality, Interaction, and Identity

Jewitt (2009) outlines three intersecting approaches within multimodality: social semiotic multimodality (associated with Kress, van Leeuwen, Halliday), multimodal discourse analysis (O'Halloran, O'Tool), and multimodal interactional analysis (Scollon and Scollon, Norris, Jones). For all three strands culture is important, though its role not necessarily made explicit. The researches mentioned cannot be assigned to one strand only; however, to simplify the matter one might say that research within the two first approaches focuses on the semiotic means and the discourse system as a set of organizing principles guiding our social meaning making, whereas the main concern of the latter approach is the contextualized and culturally embedded nature of human action.

As our tools for data gathering and analysis get more and more sophisticated, combined with the turn to qualitative and ethnographic studies, it is not surprising that applied linguistics has become more concerned both with multimodality and culture. Multimodal interactional analysis is an illustrative example of this. One of the key theoretical developments within this field is mediated discourse analysis or MDA (Scollon & Scollon, 2002, 2003). Scollon and Scollon (2002, p. 1) describe MDA as a form of sociocultural analysis, focusing on social action. Within MDA all actions are understood to be mediated by cultural tools (or mediational means). Cultural tools are semiotic tools ranging from language to material objects; social action is seen as any action performed by a social actor through the use of cultural tools. Within this approach language in a traditional sense has no primacy above other cultural tools. Scollon and Scollon (2003) show how the use of computer technology in Alaska changed social practices. Originally, this technology was designated to the administrative culture of education, but it proved to be well suited for creating new learning environments for students who were not comfortable with the panopticon classroom interaction order (the teacher-centered class where the teacher controls the interaction). Students who had no voice in the classroom setting because the interactional patterns were so different from the cultural codes of their everyday lives used technology

as a means for academic discussions on their own terms. Hornberger (2006) describes similar processes of alienation in school settings, telling the story of a Quechua girl who hardly ever spoke at school, but who, when Hornberger visited her in her home, talked non-stop, telling stories in Quechua, showing Hornberger objects in her home while performing other actions such as looking after her younger brother. Hornberger (without using the term “multimodal”) carried out a multimodal analysis of this girl’s actions in different cultural contexts, where language and interactional patterns differed. The girl’s languages and practices can be understood as cultural tools for interaction and identity construction, and the degree of access to these tools enables or limits her actions. Cope and Kalantzis (2000, p. 204) echo Hornberger’s observation when they write: “Individuals have at their disposal a complex range of representational resources, never simply of one culture but of the many cultures in their lived experience.” The authors are part of the New London Group (with, among others, Norman Fairclough, James Gee, and Gunther Kress) who coined the term “multiliteracies” to address the increasing salience of linguistic and cultural diversity and the increasingly multimodal nature of communication.

The interrelationship between cultural tools, social action, and agency is also analyzed by researchers working within the MDA framework. Norris (2004) presents a framework of multimodal interactional analysis based on the study of how two women employ different communicative modes for identity construction, such as pose, gesture, intonation, material objects, and so forth, stressing that communication always is multimodal and pointing out that the social meanings of particular modes are derived from cultures and subcultures. Jones (2009) investigates how computer-mediated technology displays the body as a cultural tool (through texts, visualities, and interaction) on Web chat sites. The online space is reflexive as the participants can view themselves and assess what kind of identity they portray. Thus, the technology itself becomes a cultural tool. The use of semiotic and material cultural tools for identity construction is also addressed by Lane (2009), showing that when language shift occurs, there are still other means than language available for the construction and negotiation of identities. A common denominator for all these researchers is the focus on how human interaction and meaning making are carried out through different cultural tools, hence their use of multimodal approaches.

Conclusions

Multimodal analysis, both as a research field and as a methodological approach, is a result of the processes resulting in single central objects of analysis such as culture and language losing primacy. Simultaneously, multimodal analysis contributes to these processes. Both culture and language are multifaceted, intricate, variable, and multimodal, and interdisciplinary approaches are essential for addressing such complex issues. This gets brought to the fore as a result of the global flow of information, resources, people, languages, and visualities, but it is worth keeping in mind that multimodal research in itself is a cultural product, born out of and shaped by technological developments.

Multimodality and Disability

NAJMA AL ZIDJALY

Introduction

Multimodality is an analytical framework created to examine complex discourses that draw upon or consist of various visual and textual modes; the framework, according to Iedema (2003), gained ground recently due to the salience of multimodal texts brought about mainly by the advent of new media technologies and a recent turn in linguistics toward viewing communication as multimodal. Disability studies, a subdivision of medical anthropology, is a field that emerged in the 1960s and the 1970s in response to traditional conceptions and treatments of the notion of disability. Given the importance of artistic expression to healing; the role that technology can play in creating access; and the fact that people, especially those with certain disabilities, draw upon various modes other than just language to communicate, multimodality and disability have naturally been brought together in the social sciences.

Disability Studies

Disability studies as a field emerged in the second half of the 20th century to combat erroneous conceptualizations of disability as a biomedical problem instead of as a social construct, thus shifting the focus from viewing those with disabilities as the setback to constructing the disabling society as the group at fault. Though the field is of an interdisciplinary nature, the focus is a social one with an inherent activist approach. Because disability is a social construct that prevails across race, gender, and geographic boundaries, the general consensus among disability researchers is that it must thus be scrutinized in its social, cultural, and historical contexts (Barnes, Oliver, & Barton, 2002).

The shift from defining “disability” as “inability to do something” to defining it as “social oppression” was originally inspired by the functionalist sociologist Talcott Parsons (1951), whose seminal construction of sickness as a social construct with rights and responsibilities instead of simply as a medical conundrum altered the manner in which deviance was conceived. Other landmarks in the development of the social view of disability are the notable study of stigma and identity management by the sociologist Erving Goffman (1963), Michel Foucault’s (1975) studies of the birth of the clinic, and Gillian Fulcher’s (1989) “discourses of disability.” These discourses, which can be divided into four types—the medical discourse, the charity discourse, the lay discourse, and the rights discourse—lead Fulcher to argue that creating social change starts with changing how we linguistically construct disability.

The central theme that disability research collectively addresses is social exclusion—the major predicament faced by people with disabilities. This form of social abandonment or invisibility is usually precipitated by distorted ideas on the part of others of the capabilities of those with disabilities. Earlier existing sociological research that addresses this experience of isolation (Goffman, 1963; Murphy, 1990; Robillard, 1999) perpetuates a passive image of individuals with disabilities in managing such an experience; isolation is erroneously

2 MULTIMODALITY AND DISABILITY

constructed as an inevitable outcome of disability. This misrepresentation was later corrected when a group of researchers started examining the construction of the social reality of disability from a multimodal perspective. These multimodal disability studies can be divided into three areas: disability and artistic expression, disability and multimodal discourse analysis, and disability and technology.

Disability Studies and Art

Art can be a means for healing one's damaged self (Ainsworth-Vaughn, 1998). It is in fact well documented in the literature on disability and artistic expression that any form of expression, whether writing prose or poetry, or painting, self-empowers through allowing those with disabilities a means to express and deal with their pent-up emotions (Corbett, 1999). Art can also change the traditional misconceptions of disability as a simply medical problem. This was the underlying theme behind the Disability Arts movement, which started in the 1980s and is considered one of the major art movements of the late 20th century. A major example of such radical artistic work, which can play and has played a role in changing the way art and disability are conceptualized in society, appears in the seminal work by Lewis (2000). What is remarkable about the various dramaturgical strategies that Lewis analyzes in works of art by people with disabilities is that not only do they arise from a social view of disability, but also—in so doing—they challenge the dominant narrative of disability that equates disability with uselessness and stigma, and that has long held sway in theater and the social world at large.

While critics of the Disability Arts movement abound, the role that art can play in alleviating the experience of disability is unquestionable. Thus, disability research continues to dedicate itself to examining visual and nonvisual art as tools for self-expression (e.g., Diem-Wille, 2001) or representation (e.g., Crutchfield & Epstein, 2000; Halifax, 2009). Some of the more recent research that deals with the interplay between art and disability from a multimodal perspective moves beyond conceptualizing multimodal texts as simply tools for representation, or for expressing visually what one is inhibited from expressing verbally, to seeing them as communicative tools for self-empowerment especially in educational settings (e.g., Wexler & Cardinal, 2009). This is in line with current dynamic multimodal research that—in contrast to earlier research on multimodality that has focused on decontextualized texts as their unit of analysis—centralizes the interplay between images and texts (Jones, 2005), the integration of visual texts in real life practices (Al Zidjaly, 2005, in press-a, in press-b) or the transformation of meaning from one semiotic mode into another as social processes unfold (Iedema, 2003).

Disability Studies and Discourse Analysis

Discourse analysis as a field prides itself on addressing linguistic, social, and cultural discrimination. However, the role that language plays in the experience of disability has been only minimally studied. As for the part that semiotics other than language can play in the construction of the social reality of disability, until very recently it has been almost completely ignored. An exception in drawing upon multimodal frameworks to address the experience of disability—particularly cognitive and motor disability—is Goodwin (1995, 2001, 2011). Building on conversation analysis and ethnomethodology, Goodwin's seminal examination of the interplay of the semiotics of gesture, gaze, pointing, and other bodily movements, in interactions involving an aphasic man with limited vocabulary and his caregivers, demonstrates not only the co-construction of meaning but also how dynamic social practices unfold in interaction where nonverbal communication plays a role. Thus, Goodwin's work has played a major role in developing the current dynamic approach to multimodality that advocates examining multimodal texts and interactions in their situated use.

Other notable studies that have successfully combined textual representation with social construction, leading to critical and socially driven multi-semiotic discourse analysis, are Everts (2004) in the area of visual disability and Keating (2003) in the area of hearing disability. In order to find the origin of communicative difficulties in blind-sighted communication, Everts (2004) applies a multimodal framework to interactions involving a blind person and her sighted friends. Everts's analysis demonstrates that the root of the social exclusion of blind people is the lack of access to the visual semiotics of face-to-face interaction, such as gaze, turn taking, and gesture, that blindness causes. Her analysis thus demonstrates, first, that—contrary to widely held beliefs—speech and hearing are insufficient to guarantee equal access to conversational participation and, second, that by identifying discursive practices that can cause linguistic marginalization, one can begin to address and in turn rectify communicative problems across ability status. Similarly, Keating (2003) demonstrates through analyzing gaze, gestures, and turn taking across ability status that unshared sociolinguistic practices and hearing-oriented participation frameworks are crucial aspects of communicative failure between hearing and deaf children in mainstream elementary school settings. Both of these multimodal studies point to the necessity for hearing and sighted people to develop communicative skills that accommodate the deaf and the blind for proper inclusion to take place.

Disability Studies and Technology

Research that addresses the relationship of new media technology to disability falls into two camps. Many believe that new media technology alleviates disability through masking disability, equalizing power, and creating independence (e.g., Sproull & Kiesler, 1986; Grimaldi & Goette, 1999; Ford, 2001). Others, however, take a more skeptical stance, arguing in some cases that technology can even create disability (e.g., Kaye, 2000; Goggin & Newell, 2003; Seymour & Lupton, 2004). Al Zidjaly (2005) notes that most of this research, however, merely speculates about the beneficial or ineffectual role that technology plays in the lives of those with disabilities. To understand the exact relationship between technology and disability, she argues, it is critical to identify specific technology-related actions that people with disabilities recognize as being of use to them personally, using the frameworks of mediated discourse analysis (Scollon, 2001) and nexus analysis (Scollon & Scollon, 2004), which focus on the action that people take at a specific moment. Al Zidjaly (2005, 2007) does exactly that as she examines music videos, created by a quadriplegic man from Oman using Microsoft PowerPoint software, as tools of agency via self-expression and defiance of oppressive societal beliefs surrounding disability. In Al Zidjaly (2011, in press-a, in press-b), she goes one step further by conceptualizing visual texts as mediated actions that are strategically used to arrive at intended outcomes, not just as self-expression tools. This multimodal analysis, from a mediated discourse perspective, reveals the complexity of the relationship between technology and disability, highlights the agency of those with disabilities, demonstrates how people with disabilities create inclusion through technology, and develops the current dynamic approach to multimodality.

The relationship between technology and disability has also been addressed from a discourse perspective. Bowker and Tuffin (2002), for instance, examine through online questionnaires how people with disabilities psychologically manage their disabilities online. Their analysis highlights the value that people with disabilities place on being able to leave their impairment out of the dynamics of social interaction, which constructs disability as an aspect of identity to be hidden or revealed. Jones (2011) compares the academic and popular discourses surrounding the nature of the relationship between disability and technology with how people with disabilities themselves talk about their experiences online. His analysis reveals that the reality of disability in cyberspace is more complicated than the discourses of social leveling, accessibility, and empowerment used to talk about

them. As a result, he suggests analyzing what people with disabilities actually do, using the framework of mediated discourse analysis to get at a better understanding of the connection between technology and disability (see Al Zidjaly, 2005, 2011, in press-a, in press-b) to analyze. Al Zidjaly (2010) further draws upon sociolinguistic perspectives to conduct a case study to see both the precise effect the Internet is having on Muslim identity and how a person with a disability is able, through the Internet, to manage a religious identity that showcases the fact that there is more to him than just being a man with a disability. All this research points to the necessity of including people with disabilities in the discourse of technology and disability.

Concluding Remarks

Since its inception, disability studies has faced numerous criticisms (Lester, 2002). It has been suggested that it has outgrown the social model of disability, which desperately needs updating to keep up with the politics of the 21st century. The social model's failure to recognize physical impairment has had counter-effects by neglecting many types of disabilities, such as illness and cognitive disability. The field has additionally been criticized for failing to engage successfully with other social movements such as those against racism and homophobia. Finally, research connecting multimodality and disability is still limited despite the fact that using multimodal discourse analysis highlights personal agency, which is especially important in the context of disability, where personal agency is often underestimated or denied. Future research on multimodality should emphasize the necessity of going beyond single modes and artistic accomplishments into how these resources are used in real life. This applies to all kinds of texts, co-constructed by all kinds of individuals. Analyzing visual texts as mediated actions instead of mere means of self-expression, healing, or representation, for example (as suggested by Al Zidjaly, 2011, in press-a, in press-b) also shows how disability is indeed a social construct. This adds to the current dynamic approach to multimodality, which uncovers a detailed understanding of visual texts but also has applied elements, while achieving too a more fine-grained understanding of the interconnections between multimodality and disability.

Multimodality and Displayed Art

MICHAEL O'TOOLE

In the 1970s and 1980s M. A. K. Halliday's systemic functional (SF) grammar was being used extensively for discourse analysis, critical discourse analysis (CDA), and stylistics of both literary and nonliterary texts. These all involved a commitment to the close lexicogrammatical analysis of the selected text itself and understanding it in its sociopolitical or literary context, or both.

By the mid-1980s the proliferation and rapid dissemination of texts combining language and visual or aural modes and the relevance of this for education led to the emergence of a new branch discipline known as multimodality. As the name implies, it involves a focus on nonverbal texts (works of art, diagrams, buildings, cityscapes, orchestral music, ritual processions) or mixtures of the verbal and nonverbal (adverts, news articles, Web sites, film and TV sequences, museum displays).

From his earliest writings, Michael Halliday makes clear with examples from musical scores and menu layouts that he regards his SF model of language as a general semiotic model (e.g., Halliday, 1985, pp. 1–18). After using SF for two decades for the analysis of literary style (O'Toole, 1975, 1976, 1982) and for CDA (O'Toole, 1985), O'Toole became convinced by the mid-1980s that the model could be used for the analysis and sociopolitical—indeed, personal—interpretation of paintings, sculptures, and architecture. His analyses of Russian and English narrative fiction in the 1970s and 1980s had been strongly influenced by Russian formalist and Prague School theory and practice between 1920 and 1940. The Russian and Czech scholars had insisted that literary study should no longer be dominated, as it had been in Russia and the West, by social history, writers' biographies, or the comparison of periods and genres, but should focus on the mechanics of the individual literary text (*priyomy*, or literary devices, as they called them). Every structural, narrative, or rhetorical device had a function within the whole work and the accumulation of functional tendencies would point to a dominant of the work. O'Toole saw the relevance of this approach for the study of multimodal art. Moreover, the formalists did not limit their studies to verbal works of art, but engaged in the analysis of film and stagecraft (Eikhenbaum, 1982).

Despite the important theory of functions in language of Roman Jakobson (1960, pp. 350–77)—himself a founder and key figure among the Russian formalists and Prague structuralists—there was, however, no fully realized grammar that could account for the linguistic details of style in literary texts until Halliday's groundbreaking work of the 1960s, most fully articulated in Halliday (1971; 1985); and little in the way of frameworks for the study of visual art.

Another important influence on the development of an approach for multimodal analysis was O'Toole's early engagement with multimodality in the 1960s, when he was one of the pioneers of audiovisual methods in language teaching, designed flash cards, and composed and performed songs for a BBC radio Russian language course, *First Year Russian*, subsequently *Passport to Moscow* (O'Toole & Culhane, 1972).

What started in February 1986 as a tentative seminar with SF and art theory colleagues at Sydney University outlining a theory for analyzing a modern Australian painting became, via many conference papers and articles, O'Toole's book *The Language of Displayed Art*

2 MULTIMODALITY AND DISPLAYED ART

(1994) and the CD-ROM *Engaging With Art* (1999) (second edition of both, 2010). The core of O'Toole's argument was that Halliday's (1971) chart of functions and systems for language could be adapted, with changes appropriate for different modalities, as a basis for the analysis of visual texts. As with language texts, it is not the labeling of particular components of the visual text as such, but the recognition of areas of semantic/semiotic convergence and divergence between the realizations of the functions that provides a focus for interpretation.

As with many shifts in theory, much of the motivation for this move came from outside:

1. The author felt that art history, with its obsession with archives, iconography, biography of the artist, details of commissioning and ownership, "movements" and chains of "influence," had distracted people from "thinking with their own eyes" and attending to what was actually on the canvas—rather as the Russian formalists had criticized the approach to text of the literary critical conventions of their day.
2. Panofsky's (1939/1972) much acclaimed dream of getting beyond iconography to iconology was not being realized because adequate tools were not available.
3. Attempts at a "semiotics of art" based on Peirce's (1994) distinction between icon, index, and symbol were equally primitive and inflexible.

The Language of Displayed Art explores the "grammar" of the visual arts of painting, sculpture, and architecture, proposing that as viewers we simultaneously read three different kinds of meaning in them:

- what is represented (representational meaning),
- how it engages us (modal meaning), and
- how it is composed (compositional meaning).

Artists are able to communicate with us because each of these types of meaning is realized through particular systems of choice in a visual language shared by artist and viewer. Thus, representation may involve portrayal, scene, or action; modally we may be drawn into the depicted world through devices of framing, light, focus, color, or perspective; compositionally the work is integrated, or "makes sense," through geometries of scale, juxtaposition, parallelism, and the relations of figure to frame (see Figure 1).

It is clear from Figure 1 that the names of the functions and systems in a grammar of displayed art must be quite different from those that systemic linguists deploy for studying texts of verbal language. Indeed, the rank scale of units in the left-hand "Units" column assumes that they are defined more "fuzzily" than the structurally defined units of natural language, at least in its written forms.

The Language of Displayed Art sustains a continuous argument with the dominant paradigm of art history. On the one hand, facts about the commissioning of and social or literary inspiration for artworks, contemporary schools and styles of art, and even the biography of the artist may provide essential background to our understanding of a painting, sculpture, or building. On the other hand, in the dominant discourses of art—catalogs, monographs, histories, journalism, visual media, gallery tour guides, and education—this background tends to dominate and distract from our personal, individual reading of the particular work to such a degree that we feel helpless without it. A coherent, consistent, and well-articulated semiotic approach gives power back to the viewer: We must learn to trust our own eyes. What is more, the SF model provides a coherent and well-defined terminology for articulating our personal readings.

Outside the actual verbal text, Halliday argues that what we talk and write about and the language and discourse genres we tend to use in a given period configure the map of

Function Unit	REPRESENTATIONAL	MODAL	COMPOSITIONAL

the current “social semiotic.” If we extend this notion to the subject matter and dominant stylistic features (through systems of representation, modality, and composition) in paintings, sculptures, and buildings, we can extend the social semiotic to include its visual modes. This, of course, brings us back to art history, but an art history that is constructed from a period’s artworks, not one imposed on them from the historical or biographical archive.

The first four chapters of *The Language of Displayed Art*, subtitled “Perceptions,” show visual semiotics at work in painting, sculpture, and architecture. Despite the popularity of Botticelli’s *Primavera* (1478) and, perhaps, because of the vast literature that it has generated, individuals find it difficult to “read” the work in a coherent and satisfying way: Historical knowledge about Florence under the Medici competes with the little we know about Botticelli’s life, or with philosophical trends in fifteenth-century Florence, or with myths from Ovid’s *Metamorphoses* which the artist was using to construct a story line, or with the arrangement of human figures and geometric relations within the frame of the painting. Chapter 1 helps the reader-viewer to “think with their own eyes,” noting and combining the ways the artist draws us into the world of the work (the modal function), what that world consists of (the representational function), and the way these are constructed into an aesthetic unity (the compositional function). O’Toole argues that, used consistently, this semiotic framework of analysis makes possible both satisfying individual interpretations and dialogue between viewers, who will have properly articulated grounds for their disagreements.

Turning to sculpture, the second chapter, “Bodily Perceptions,” applies a similar framework—though with a terminology appropriate to the distinctive substance, forms, and relationship to the spatial context and the position of the viewer of the art of sculpture (see Figure 2). As with the *Primavera*, the analysis of the four chosen works (by Bondarenko, Barbara Hepworth, Rodin, and Nigel Helyer) is much more detailed and takes interpretation much further than any earlier critical literature.

4 MULTIMODALITY AND DISPLAYED ART

Function Unit	REPRESENTATIONAL	MODAL	COMPOSITIONAL
WORK	Process (action/event/ existence/relation) Theme (religious/ magic/civic/political) Peripeteia (narrative turning-point)	Scale (to human) Mass Equilibrium Modality Palpability 'Address' Message	Volume (relation to space) Proportion (relation to setting) Independence Openness/Closure Fixed/Mobile Cohesion Material
FIGURE	Participants (agents/ patients/existents) Body (anthropomorphic/ zoo-morphic/ biomorphic/ inorganic) Act Movement/Stasis Position	Scale Characterization Mass Equilibrium Expressiveness Address Vitality Line Solidity Relation to Light	Relative position in Gestalt Parallelism Static/Dynamic Fixed/Mobile Rhythm Material
MEMBER	Basic Physical Forms (parts of the body/ objects natural forms/ machine parts/ geometric forms) Drapery	Fullness of Realization (detailed/stylized/ attenuated/abstract) Raw/Polished Stress Factors	Texture Rhythmic Relations Material Qualities

Figure 2 Systems and functions in sculpture © O'Toole 2010

In the case of architecture, buildings function much more like texts of language than the purely "displayed arts" of painting and sculpture (see Figure 3). They function

- as use, that is, experientially;
- as self-expression, that is, interpersonally; and
- as harmony, that is, textually.

It therefore seems reasonable to use the same labels for the semiotic functions as Halliday does for the semantic functions in language, even though the actual systems of choices which realize these functions are radically different from those of lexicogrammar.

The architecture model is tested in an analysis of a designer home (1990) in Perth, Western Australia; Alvar Aalto's Enzo-Gutzeit office block (1960–2) in central Helsinki; and Le Corbusier's chapel to Notre-Dame du Haut (1950–5) at Ronchamp in eastern France. These buildings are sufficiently different in their use, the facades they present to the world, and their structure and finish to test and extend the analytical model being proposed. The theory and the description are dialectic. Once again, we start with a theory, but the specifics of the description of a particular building, as of particular paintings and sculptures, force adjustments to the theoretical framework.

In the process of mapping the systems at work in various functional areas of a building, it is not necessary to account for every single detail, as though the chart was a kind of checklist. We find rather that the most interesting features, visually or socially or politically, tend to cluster in particular areas of the chart, crossing boundaries of rank and function. These are sometimes referred to as "hotspots" of meaning. They relate to the formalist literary concept of "dominant functions."

Units	Functions	EXPERIENTIAL	INTERPERSONAL	TEXTUAL
BUILDING	Practical function: Public/Private; Industrial/Commercial/Agricultural/ Governmental/Educational/Medical/ Cultural/Religious/Residential; Domestic/Utility Orientation to light Orientation to wind Orientation to earth Orientation to service (water/sewage/power)	Size Verticality Chthonicity Facade Cladding Colour Modernity Exoticism	Orientation to neighbours Orientation to road Orientation to entrant Intertextuality: reference mimicry contrast	Relation to city Relation to road Relation to adjacent buildings Proportions Rhythms: contrasting shapes, angles Textures: rough/smooth Roof/wall relation Opacity Reflectivity

Figure 3 Systems and functions in architecture © O'Toole 2010

The final chapter of "Perceptions" attempts something quite different. Rather than analyze a single form of displayed art, it attempts to compare two radically different art forms, a poem and a painting, which share a single subject: the myth of the fall of Icarus. This makes it possible to engage with the challenge of comparing a Hallidayan lexicogrammatical analysis with the semiotic model for the analysis of painting proposed in chapter 1. W. H. Auden based a major section of his poem *Musée des Beaux-Arts* (1939) on the painting *Landscape with the Fall of Icarus* by Pieter Brueghel the Elder (ca. 1558). As the analysis reveals, the framing and marginalization of the moment of tragedy, the disappearance of Icarus into the waves of the Aegean sea, and the play with vocabulary and painting styles reveal considerable isomorphism, but the different mental processes involved in following a linear text and scanning a painting affect the reader-viewer quite differently. The availability of congruent SF models for the analysis of verbal and visual texts, however, makes the comparison meaningful.

The second half of the book ("Conceptions") engages with a number of theoretical issues raised by the application of SF semiotic analysis of displayed art, while continuing to analyze and interpret a further eight paintings. O'Toole considers the relationship between a close focus on the individual art text and the established paradigms of art history, criticism, and teaching. It argues that, despite their divergent aims, the semiotic analysis of paintings has to be enriched by what we know of the artist and the social and philosophical history of his period. On the other hand, most of the dominant discourses of art—whether in the media, the schoolroom, the gallery, the academy, the archive, or the auction house—prioritize their own practices and minimize the close scrutiny of the text to such a degree that even the self-motivated viewer feels disempowered by all that expertise. A semiotics of art, as practiced in *The Language of Displayed Art*, aims to be theoretically explicit in its approach to the individual work or a comparable group of works, and recognizes that it is itself a cultural practice alongside the dominant cultural practices of art history, criticism, and records of provenance and ownership.

A great deal of art history compares works with works within one artist's oeuvre, or artists with one another, or one period with another. The chapter entitled "Modes of Comparison" assesses to what extent meaningful comparison of paintings with a particular central theme is possible despite distances between the periods and cultures within which they have been conceived. The anti-chronological bias of the book and its method is underlined by the dates and sources of the three paintings chosen: the Australian Russell Drysdale's *The Gatekeeper's Wife* (1965); a Russian suprematist poster, *Arrange a "Red Gift Week" Everywhere and All Over* (1920–1); and Giotto's panel in the Arena Chapel in Padua, *Noli me tangere* (1304–6). All three depict two human (or quasi-human) figures engaging with each other. This engagement engages us, the viewers, in particular ways which relate to both their subject matter and their composition, and, ultimately, to the ideological soil from which they have sprung.

O'Toole then considers how Halliday's concept of the "social semiotic," which is itself reconstructed from the systems chosen for making pictorial meanings in a given era, relates to Marxist and Freudian constructions of the "viewing subject" which are imported, as it were, from outside the art forms as such. Analysis is not abandoned at this point, however, since the author attempts to define the main parameters of the social semiotic for each of the paintings analyzed up to this point in the book.

The final chapter confronts the important question raised by a "functional" approach as to whether certain paintings display "monofunctional tendencies." Is Canaletto's focus on representing real-life events in *A Regatta on the Grand Canal* (ca. 1735) comparable to Andy Warhol's *Campbell's Soup Cans* (1962) in its dominance of the systems of the representational function? Does J. M. W. Turner's *Snow Storm* (1842) engage us in the same way—that is, with the same systemic choices in the modal function—as Bridget Riley's *Cataract III* (1967)? And does the dominance of the compositional function in Piet Mondrian's *Composition with Yellow, Blue and Red* (1937–42) work in the same way as that of Jackson Pollock in *Phosphorescence* (1947)? Or is "functional dominance" just a matter of degree—as the Russian formalists would have insisted—since all of these six paintings require the other two functions for us to interpret them and for them to count as works of art?

The advantages of using a CD-ROM (O'Toole, 1999; 2010) for exploring and teaching about the arts are the high quality of digital images and the flexibility of the hypertext. A book requires a linear argument, whereas a CD-ROM allows—indeed, encourages—the user to move backward and forward between the logical argument and the whole painting or its details, other charts and illustrations, and, in the case of *Engaging with Art*, a "virtual gallery" of 28 paintings, for which the users can try out the analytical skills they are learning from the program. Thus, the hypertext shares with an SF chart and with a painting the possibility of moving both across the whole model and in or out between the whole and the details.

Since the publication of *The Language of Displayed Art* O'Toole has published analyses and reinterpretations of:

1. paintings—Rembrandt's *The Night Watch*; Chinese landscape painting; Julie Dowling and other recent Aboriginal painting; John Longstaff's *Breaking the News*; the logic of Magritte;
2. sculptures—*The Bronze Horseman* (St. Petersburg); institutional sculpture (Perth); English Gothic misericords;
3. architecture—Sydney Opera House; a Japanese *ryokan* (guest house); Noyori Conference Hall (Nagoya); the language and architecture of *Fawlty Towers*; and
4. the significance of computer-generated images in the television comedy series *South Park*.

Many postgraduate students and colleagues have produced dissertations and papers applying O'Toole's model to various forms of displayed art, including painting from several cultures, cemetery sculpture, domestic architecture and design, civic design, drawing, museum design, advertisements, children's book illustrations, and so forth. So far no full-length books have followed—or argued with—*The Language of Displayed Art*.

The rapid development in the 1990s of new and cheaper modes of display, retrieval, and reproduction of visual images, including film and TV, led to groundbreaking work by Anthony Baldry and Paul Thibault (2006), Jay Lemke (1990), and Kay O'Halloran (2004) on film, television advertising, and Web site design.

Since the late 1980s, the texts studied for "English" in schools and universities have included advertisements, diagrams, songs, political speeches and manifestos, film clips, and so forth. *Reading Images* by Gunther Kress and Theo van Leeuwen, originally published in 1990 but expanded into *Reading Images: The Grammar of Visual Design* (1996), and their *Multimodal Discourse: The Modes and Media of Contemporary Communication* (2001) concentrated on these areas of multimodal discourse. Working within the SF framework, but without Halliday's and O'Toole's charts of systems and functions for each mode of discourse, their work has been highly influential. Whereas O'Toole's work has primarily involved a search for open interpretation of art forms, theirs has involved a search for the ideological underpinnings of the multimodal text.

A crisis in the theory and management of museum display in the 1990s led to an important stream of multimodal work in this area by Louise Ravelli, Mari Stenglen, and others (Ravelli, 2006). Peter White and a group of colleagues and graduates in Sydney and Adelaide were advancing the framework for newspaper articles with photos.

Apart from the intrinsic value of analyzing nonverbal and multimodal texts with the SF framework, an outstanding advantage revealed by its application in undergraduate and graduate programs at Sydney and Macquarie Universities, the University of Technology Sydney, the University of New South Wales, Murdoch, Singapore, Helsinki, Swansea, and Pavia has been the way it illuminates the theories, methods, and terminology of *verbal* textual analysis for students who are not always at home with the complexity and subtlety of linguistics. Sometimes it is a revelation to see how one element in a painting may be simultaneously representing something, engaging us modally, and contributing to the overall composition—just as often happens in language.

Multimodality and Film

JOHN A. BATEMAN

Film is an obvious candidate for consideration as a multimodal artifact. Even from the earliest “silent” films at the turn of the 20th century, musical accompaniment was common and this, combined with the subsequent use of intertitles as the form developed, already constituted a rich multimodal scenario. The current state of film—with its increased visual scale and resolution, multichannel sound, and now the rise of 3-D—pushes this multimodality still further and offers one of the most complex and tightly structured meaning-making practices developed so far. Both as a challenging object of multimodal study and as an example *par excellence* of multimodal meaning-making at work, film makes considerable demands on any theory and practice of multimodality and raises a wealth of open issues and questions concerning how best the functioning of multimodality can be explored and characterized.

Film also directly raises specific problems concerning just what “multimodality” is. Although many traditional approaches to multimodality have tended to conflate modalities with *sensorial* modalities, that is, distinguishing visual, acoustic, tactile, and so on, providing accounts of film quickly forces us to move beyond this. For example, within the acoustic channel, film theory already commonly distinguishes between ambient sounds of the events being recorded and the nondiegetic (i.e., not present in the world of the film) accompaniment of the musical soundtrack. Moreover, among the ambient sounds it is generally useful to distinguish between sound effects and the spoken natural language constituting the dialogue of the film. Such spoken language can then also be nondiegetic, for example, when a film is employing a voice-over or similar. All of these potentially distinct semiotic modes are carried by the sound channel but nevertheless enter into differing relationships with the information being carried by other modes and channels copresent in the film. The visual channel may also be decomposed in various ways. If written language is employed within the visual channel, then it is most appropriate to treat this with the tools and methods from linguistics. If the film is set in 17th century Europe, then it may be beneficial to employ information about the modes of dress from that time, and so on. As a result of this diversity of contributions, any simple characterization in terms of the senses is not only unhelpful, it may even be misleading in that it disguises commonalities in information presented across superficially quite different sensorial channels.

Another indication that film is a truly multimodal artifact is that specific *combinations* of these distinct modalities are commonly employed for creating further, second-order effects—for example, the ambient sounds may be presented “iconically,” in that nearer objects make louder noises than objects far away, but it is equally possible within film to reverse this relationship for cinematic effect; or the sounds may not be presented synchronized with their visual correlates; or the sounds may even be used to create structural unities in counterpoint to the visual structures presented, as when a line of dialogue links across distinct shots or portrayed locales. All of these contribute to the complexity and power of the multimodal artifact that is film and establish good grounds for seeing film as a genuine semiotic hybrid, with new meaning possibilities arising out of the combination of modes available. Multimodal meaning-making has been described by Lemke (1998) as a process of “multiplying meaning”—but how precisely such a multiplication should

2 MULTIMODALITY AND FILM

operate is still very unclear at this time. Few frameworks for discussing multimodality are sufficiently developed to address this range of phenomena, although the sociofunctional semiotic tradition and its development of more refined notions of semiotic modes has begun to make some inroads here (van Leeuwen, 1985, 1991, 1996; Bateman, 2010). Film provides a wealth of locations where an elaborated notion of multiplying meanings is necessary and so stands as a critical test bed for any theory of multimodality that may be proposed.

From the perspective of film theory, issues of multimodality have also been long addressed in film study's own terms and it is particularly important for newer proposals within theories of multimodality to draw on this foundational work.

Early in the development of film theory, there were attempts to draw out the specific contribution of the filmic medium in a way that would allow its artistic credentials to be demonstrated, that is, to show clearly how film was more than just a photographic record (Pudovkin, 1926). Much of this work fell foul of the precepts of "medium essentialism," whereby individual arts were meant to have specific properties due to their material substrates, which then made them suitable for certain kinds of expression rather than others: For example, it was proposed that painting "should" concern itself with space and not with time, whereas poetry "should" concern itself with time and not space. In the case of film, this led to proposals of realism as being the "natural" highest form conceivable and so, to be "art," films should be realistic (Bazin, 1967; Kracauer, 1997). A useful deconstruction of this prescriptivism is given by Carroll (1988). In terms of multimodality, this kind of approach can also be criticized as combining, inappropriately tightly, more abstract patterns of signification with the less abstract material substrate used for realizing those patterns (Bateman, 2010).

A quite different angle on exploring multimodality in film was taken within film semiotics. Here work particularly by Christian Metz in the 1960s and 1970s sought again to isolate just what the specific contribution of film in contrast to other semiotic artifacts was—although this time not for the purposes of medium essentialism but simply to provide an accurate characterization of film as such. Metz's approach was to consider film as a combination of distinct semiotic modes, which could then be ordered along a scale of "specificity" according to the range of distinct semiotic artifacts they could be applied to (Metz, 1974). Some modes span a broad range of diverse artifacts, including many artifacts other than film; others were more specific and apply to a narrower range of artifacts. Film "as such" was then defined in terms of a specific combination of semiotic contributions rather than being considered a unique code in its own right.

With respect to the visual track, for example, Metz isolated five distinct classes of semiotic artifacts in this way. The most general, Metz's group 1, covered all artifacts relying on *visual iconicity*; this involves all depictions that are intended to bear some relationship of "resemblance" to what is being portrayed and includes photographs, painting, drawings, television, comics and, of course, film. Two more specific restrictions of this are then group 2, *mechanical duplication* and, within this, group 3, *multiplicity*. To the former belong all artifacts that use photographic or other "automatic" technologies for the creation of their images; to the latter belong artifacts that rely on the possibilities offered by employing *sequences* of images rather than single images, thereby distinguishing between, for example, single photographs and the photonovel. Within this latter group, Metz proposed a further subtype: *movement* (group 4), where the image itself includes movement, that is, actually moves. This then served to distinguish between comics and films—both include multiple images, but only the latter involves the moving images. Film and television were then the specific result of combining group 3 and group 4 into group 5.

Although this early account moves very much in the direction of some more recent decompositions of the notion of semiotic modes, some changes to improve its generality

Figure 1 Revised version of Metz's (1974) characterization of more or less specific semiotic modes contribution to film

also need to be considered. For example, Metz's inclusion of group 3 within group 2 appears to have been simply a generalization motivated by restricting attention to the majority of narrative films: There is actually no need to insist on multiple sequences since it is quite possible to produce "single take" films—a possibility made simpler these days by the use of digital recording devices. Metz was also not considering animations, which allowed him to assume mechanical duplication; with today's computer graphic capabilities where there is no "duplication" involved and even with earlier animated cartoons, this feature fails to apply and so cannot be considered an essential component of film. Thus, following Buckland's proposal of a graphical representation of the modalities involved rather than Metz's somewhat verbose textual description (Buckland, 2000), a characterization of film might be set out as in Figure 1.

In addition to these features come the separate contributions of the sound track and combinations of the visual and aural channels. And, amongst these areas of semiotic contribution, several already make close contact with linguistic descriptions in general, not necessarily related to film. For example, linguistic studies of dialogue and interaction are equally relevant for the analysis of the spoken linguistic component of films. Interesting, however, is the way in which the use of this medium in film then *deviates* from natural interaction—often quite deliberately for aesthetic or other effects (Kozloff, 2000). Similar modifications occur with music—film music is employed in its own particular way in order to add meanings to the scenes it accompanies, involving emotional, structural, and cohesive functions (Davis, 1999; Gorbman, 1980). This applies to a considerable range of phenomena, even for micro-organizational aspects of interaction, such as the rate of blinking (Bordwell, 2007) and, most famously from the perspective of film and, in particular, feminist film theory, "gaze" (Mulvey, 1975).

Finally, there are now investigations of film that directly employ more results from linguistics, particularly from the areas of cohesion and discourse representation theory (Tseng & Bateman, 2010). All of these can now be expected to lead to an intensification of research into film from the perspective of linguistically inflected multimodality going far beyond the considerations of dialogue and interaction and with both theoretical and practical implications, for example in the expanding area of multimodal literacy.

Multimodality and Globalization

ULRICH SCHMITZ

Introduction

Human communication is typically multimodal. Verbal communication goes along with mimic and gesture; written text always shows a typeface more or less visually designed (Krämer, Cancik-Kirschbaum, & Totzke, 2011). Nowadays, however, multimodality often is technically produced and conveyed; thus, it becomes more complex. Moreover, socio-economic conditions and technical developments have allowed the world to coalesce more and more. Therefore, communication is becoming more global—not only for the elite. Natural languages, however, put up regional barriers against internationalization. Other sign systems (sound, music, pictures, imagery, etc.) are not as efficient as natural languages, but they are not (or are incomparably less) bound to rules, which apply only regionally. Due to digital communication techniques (as in multimodal computers and smartphones) new, variedly mixed forms of communication occur. These techniques make the multimodal nature of human communication (Norris, 2004) available and transportable via technical means—independent of space and time. Research investigating multimodality and globalization takes into account factors such as unequally weighted economical power interests, the desire for worldwide comprehension, and the claim for cultural diversity and regional identity result in partly conflictual tensions.

Multimodal Communication: Terminology and History

Whenever individuals meet in person they use all their sensory organs to communicate. Eyes understand optical (i.e., visual) signs (e.g., mimics and gestures), ears acoustic ones (e.g., sounds and spoken language), the skin understands haptic signs (e.g., a handshake or stroking), the nose olfactory ones (e.g., body odor or perfume), and the tongue understands gustatory signs (e.g., in the sexual act). Since they are particularly flexible and differentiable, visual and acoustic means have turned out to be dominant mediums of communication in the course of evolution. Beyond personal face-to-face interaction—with growing communication distance due to advancing technical devices—channels other than visual and acoustic are not used because they cannot be easily engineered.

Multimodal communication researchers discriminate among mode, medium, and sign systems. The mode describes the physical basis (e.g., optic, acoustic), the medium the technical instrument (e.g., telephone, television), and the sign system describes the chosen repertoire of signs including the conventions of their usage (e.g., the lexis and grammar of spoken language). Mode, medium, and sign systems are reciprocally dependent on each other: the better they match, the more efficient communication is. As all of them have different advantages and disadvantages, the history of communication can be described as a creative-experimental development of different mixtures, whose compositions evolved from social necessities (e.g., acceleration, intensification, and differentiation of social traffic, extension of the radius of communication in space and time), and technical inventions

(script, letterpress printing, telephone, radio, computer, etc.) (Leroi-Gourhan, 1964–5; Ong, 1982).

During this productive competition countless forms of communication (from dance and theatre to flyers and encyclopedias to posters and family music) emerged, which make variable use of the different modes and sign systems. Because large quantities of written text could be reproduced moderately cheaply due to the invention of movable type (resulting in an alphabetization of a large part of the population) it was mostly written pieces of communication (letters, documents, books, etc.) which—concerning quantity, status, and reputation—gained an almost monopolistic position within the whole communication system beyond face-to-face in the Western world in the second half of the 20th century.

This fact promoted the naive belief that communication typically takes place monomodally or at least depends on written (or alternatively spoken) texts. Within this tradition philology and applied linguistics concentrated on written or spoken language and suppressed other sign systems completely, although they are always involved in some way, in extreme examples only in a very reduced form (e.g., monotonous typography, spare layout or hardly modulated voice, uniform speech rate, etc.).

From the middle of the 19th century until today (with increasing acceleration), advances in printing technology, the invention and advancement of photography and film, telephone, radio, and television, as well as of many other audio-visual media including the semiotic general-purpose machines of computer and smartphone, made nonwritten elements of human communication amenable to production, reproduction, and worldwide distribution, however, only in an acoustic and visual form. As a result, the multimodal character of human communication is highlighted by researchers in communication science and applied linguistics (e.g., Ventola, Charles, & Kaltenbacher, 2004; Roth & Spitzmüller, 2007; Deppermann & Linke, 2010). “Multimedia,” in contrast, is a buzzword of everyday speech, which does not distinguish between the various modes of communication and different technical devices. Not all new forms of communication are predominantly multimodal, though; consider SMS, chat, and e-mail, even if symbols, pictures, videos, and audio files may be included as the case arises.

Multimodality and Globalization

New media, available worldwide as far as the digital divide allows it, promote the international expansion of the dealings of individuals, goods, finances, and services amongst the privileged. This globalization creates new conditions and requirements for worldwide communication (Coupland, 2010).

Verbal messages fail to meet the needs for the new conditions; instead, they usually succeed in communicating only regionally, because verbal texts, whether spoken or written, depend on complex grammars. In order to function reliably across time, they change very slowly and are usually bound to historically developed and regionally more or less localized communication communities. Thus they hinder economic and cultural tendencies of globalization, which accelerate constantly. Indeed, the ambit of languages could be extended, but in doing so ecological diversity disappears. Furthermore, foreign languages can be learned, but this usually affects expressiveness and communicative differentiation. A worldwide lingua franca could be established but artificial languages did not succeed and natural languages (currently English) tend to entail pidginization while different varieties evolve (global Englishes) simultaneously. In all cases the grammar and lexis of single languages impede worldwide communication (Fairclough, 2006).

Iconic signs (e.g., prototypical pictures) do not require distinct conventions in a community because they structurally resemble their denotation. Photographs, for example (in the press and in advertising), are understood all over the world, although they—because of cultural patterns and previous knowledge—are filtered and interpreted in various ways. Even (iconic or abstract) painting, music, and other nonverbal messages, mono- or multimodally composed, do not require any knowledge of rules learned in advance in order to be understood; yet culturally different styles and habits play an important role concerning the quality of understanding. Nonverbal messages can be (verbally) interpreted and explained, but they cannot and need not be translated.

However, nonverbal sign systems have disadvantages for communication. Since they do not possess the typical double structure of phonemes and morphemes (or their written replication), they can only be cross-referenced to the world in a limited way. Either only a few nonambiguous signs are available (e.g., arrows, pictograms), which do not require or qualify for grammatical organization, or the ability to act as a reference is not intended by the developer (e.g., music, architecture).

On the other hand multimodal communication utilizes synergetic effects. Wherever languages alone are inefficient or intelligible only regionally, and wherever one cannot sufficiently distinguish semiotically by other visual or acoustic means, further coalitions and metamorphoses of variable modes can be employed—especially those of text, image, sound, or all combined (cf., LeVine & Scollon, 2004; Kress & van Leeuwen, 2006; Machin & van Leeuwen, 2007). Our ancestors knew this already. Take the “Cave-Canem” mosaic in Pompeii, Gregorian chants, or balladeers, for example. Even at the zenith of letterpress printing multimodal constellations beyond face-to-face communication played an important role in social intercourse. Maps connecting highly schematized illustrations of geographical structures to pictograms, proper names, and explanatory texts are examples of older multimodal communication, whose sign systems and techniques have been developed further up until the present (e.g., Google Earth).

However, modern and electronic mediums together with increasingly global communication made multimodal communication, in all its variations, the dominant instrument of public communication (Elleström, 2010; Kress, 2010). Monomodal (merely written or visual) forms of communication, in contrast, are limited in use to exclusive niches; even in libraries, museums, or churches one will have to search for them.

Multimodal Mass Communication in a Globalizing World

The more international the audience for communication is, the more multilingual the communication and also the more multimodal. Inscriptions, symbols, pictograms, emblems, guideposts, and other orientation systems, graffiti, pictures, audible warning signals, ring tones, background music, and all kinds of signs of different, often international, origins, especially at airports, train stations, traffic routes, and other public spaces, constitute an utmost dense and flexible semiotic landscape in which every pedestrian has to find their way (Backhaus, 2007; Shohamy & Gorter, 2009). This multimodal structure in particular facilitates their necessary selective orientation within the nontransparent glut of signs. Multimodal communication employs conventions, too; otherwise it could not function. But they are more flexible, more transparent, and less strict than grammatical rules. As the rules, habits and conventions of multimodal communication are protean and partly depend on the relevant situation, individuals get to know and handle them from case to case in situated communication and in specific contexts. Thus, they do not need any particular ability in advance in order to understand and produce multimodal communication (as is supposed for language acquisition).

Individuals not only participate in international environments as travellers, they also encounter globalization in their homes. Almost all goods come with multimodal character sets, be it as printing on the product itself, be it on the packaging or in additional material (labels, tags, documents, CDs, etc.) of all kinds. All mass media work multimodally. The newer the newspaper or the magazine the more complex is the interplay of text and picture, typography, and layout. Multimodal forms of communication facilitate the orientation and selection for users within huge and heterogeneous offers of information in two-dimensional communication spaces, similar to public spaces. Although there are culture-specific variants, the ergonomically best variants, which follow the rules of perception psychology rather than arbitrary rules or coincidences, establish themselves (Farkas & Farkas, 2002).

The younger a form of communication is, the more diverse and denser are the multimodal techniques (e.g., in the World Wide Web). Radio, television, and film also integrate language almost permanently into other modes. This creates new, internationally and partly globally recognizable formats. On television, the same pictures and films are often used worldwide by international agencies. On the basis of supplied storyline texts these are provided with language specific to regional needs (similar to the country-specification of identical software). In that way parts of the TV program become more alike globally. Often advertising is the most obvious pioneer of a global homogenization. It makes all modes of communication coalesce more and more, and simultaneously appearances, formats, and contents of public communication tend to be standardized intensely worldwide, even though regional marketing conditions and cultural specifics have to be taken into account in many cases. The amount of text constantly decreases in this course; major parts of the message are redeployed to other modes. The monomodalization enforced by early communication techniques tends to be reversed. Therefore medial communication, even if it is planned institutionally, is able to adjust to the habits of everyday face-to-face communication and, as a result, blends into it. Internationally identical devices and globally similar multimodal compositions permeate local everyday culture in this way—from California to big Indian cities, from South Africa to the last Yemeni village (but not vice versa).

Grammar and Design

Multimodalization by technical means results in design that has changed from an ornament to an autonomous carrier of meaning (Roth & Spitzmüller, 2007). When meaning is distributed across several modes, the different sign carriers interact and infect each other. In text-picture combinations, readers decode prototypical monomodal (i.e., nondesigned purely written) texts linearly (in the West from left to right and top to bottom) and reconstruct the fractions of the full sense bit by bit. This takes time and requires sound knowledge of written language. Viewers of pictures, however, gain a rough overall impression in the first tenth of a second, which is distinguished top-down afterwards. In text-picture combinations (e.g., in advertising posters, traffic signs or hyper-medial Web sites) both modes are interconnected by sight leading visual means (the architecture of surfaces or screen layout, typography, coloring), that is, by design. In practice this makes pictures adopt certain characteristics of texts (left-right orientation, concentration of the content on few elements, plain design of figure and ground) and texts adopt those of pictures (text design, more extensive than linear compositions, appearance, form, and content divided into small sections, modular instead of hierarchical organization, reduction, or abandonment of grammar). The extent of these metamorphoses depends on the respective type of text and picture; very often they merge into homogenous text-picture shapes (e.g., logos, banners, hyperlink signs).

International and partially globally similar conventions evolve here too. There are four reasons for this. First, pictures are not bound to languages with regional validity. Second, if there is an uneven distribution of power economically, politically, and culturally, a *pictura franca*, which appears universal but which actually conveys an aura of international—that is, West influenced—culture, can easily be propagated. Depending on the author, situation, and purpose multimodal messages attempt to find a balance between optimal global communicability and utmost local cultural identity. Third, multimodal design supports ergonomic purposes whose effects are subject to logical, pragmatic, and anthropological constants rather than to culture-specific traditions. And fourth, particular multimodal products can and should be easily communicated and intelligible: the more global their use actually is, the more homogenous the common conventions are. Thus a European is able to recognize the structure of a Chinese Web site immediately—sometimes they are able to surmise the content and even partly understand it. Provided the verbal parts are small, automatic translations, as they are offered for free on the Internet, suffice for a first approach.

Research

The connection between multimodality and globalization has been studied only rudimentarily until now. Within some sciences with very broad work areas (philosophy, semiotics, communication, and media science) this topic seems to be at the fringe. Many cultural sciences (linguistics, musicology, art history, and educational sciences) thoroughly investigate one mode, but not several in combination. Others (psychology, sociology) are typically not concerned about the means of communication. It can be a challenge to organize interdisciplinary cooperation in research as is necessary to study multimodality. Nevertheless, the number of relevant publications is rising; very often in the form of articles about individual questions concerning multimodality. Subsequent to groundbreaking older works about the history of multimodal communication (Leroi-Gourhan, 1964–5; Ong, 1982) general research results emerge from linguistic globalization research (Fairclough, 2006; Coupland, 2010) and from sociolinguistically orientated discourse analysis (Machin & van Leeuwen, 2007). Media aesthetics (Elleström, 2010) and particularly social semiotics (Kress & van Leeuwen, 2006; Kress, 2008; Kress, 2010) and works about linguistic landscapes (Backhaus, 2007; Shohamy & Gorter, 2009) usually dwell on multimodal compositions, their functions, and effects more concretely and comprehensively (also under conditions of globalization). Furthermore, an increasing number of linguists dedicate themselves to the interplay between language and other modes of communication—not only in personal interaction (Norris, 2004), in local and regional areas, but also in worldwide communication (Ventola et al., 2004; Roth & Spitzmüller, 2007; Forceville & Urios-Aparisi, 2009; Deppermann & Linke, 2010).

All these approaches should be pursued and expanded and should also learn from each other. Under the conditions of accelerating globalization human communication is becoming more complex. Therefore, the demands of communication communities as well as of individuals for communicative competence are growing. Within this process multimodality has played a limited role until now. The better we know and understand the special conditions, tendencies, and opportunities of multimodal communication within the expanding global reality of communication, the better and more consciously we can design them. Applied linguistics should bring diverse fields of research together to make them fruitful for production (e.g., text and Web design) and reception (e.g., in school and education). In doing so it will have to, like all linguistic disciplines, give up the common academic attention to spoken and written language in favor of the investigation of multimodal communication in the reality of life.

Multimodality and Hypermedia

EMILIA DJONOV

No longer reserved for hypertext that includes sound or video, nowadays the term “hypermedia” refers to any hypertext featuring both typographic and non-typographic elements and has become interchangeable with the term “hypertext.” Hypertext consists of nodes and hyperlinks. Nodes present information through verbal, visual, and increasingly also aural and kinetic resources; in other words, nodes are multimodal as they incorporate different communicative modes. On the World Wide Web, the world’s largest and most complex hypermedia environment, nodes are HTML documents, opened with a Web browser (e.g., Mozilla Firefox) and called “Web pages,” and a group of Web pages that displays cohesion and coherence (i.e., functions as a text) is termed a “Web site.” A hyperlink is activated by selecting an anchor (a visible, clickable area) on a source node, which transfers users to a target node. Nodes thus serve as an interface for navigating through hypertext.

As hypermedia permeates professional, educational, and recreational contexts, it has attracted the attention of various research fields—computer and information science; literary, cultural, and media studies; education; and linguistics—which have considered it from three perspectives: (a) as digital technology for implementing hypertext; (b) as (meta)medium, or platform for multiple media/channels of communication (e.g., aural, visual, haptic); and (c) as content/text, that is, in terms of its meaning-making potential (Lemke, 2002). Although the third perspective has received most attention in applied linguistics, the meaning-making potential of hypermedia cannot be explored in isolation from the technology and media that materialize it.

Hypermedia texts make meaning through the interplay of hyperlinks with various semiotic resources (e.g., language, typography, layout, color, sound, movement). The presence of hyperlinks, or hypertextuality, is the defining feature of hypertext, and allows designers to establish multiple potential sequences and users to forge actual paths through hypertext. A hyperlink may connect nodes that belong to the same or different texts, activate an application other than the user’s Web browser, or link existing to newly designed nodes. A user’s traversal through a hypertext environment typically includes only a selection of nodes, usually explored one at a time, from one or more texts, and may involve three commonly recognized modes of use: searching/information retrieval; browsing (that is, navigation aimed at fulfilling a specific task); and free navigation/surfing. Increasingly, through the advance of Web 2.0 formats, users can also redesign and contribute content to a hypermedia text. These aspects of hypermedia render hypermedia texts multi-sequential and fragmented, and—especially those on the Web—open-ended and transient, and challenge traditional notions of text as a linear unit confined in space or time and with strict divisions between author and audience.

While hyperlinks make explicit the presence of semantic relations within and between hypermedia texts, it is the interplay of different semiotic resources within and across nodes that can signal their meanings (e.g., similarity, generality, cause). In fact, such relations may obtain within as well as between (groups of) nodes that may or may not be hyperlinked with each other or visited in a user’s traversal through a hypertext (Djonov, 2005). For example, on a Web site’s home page, resources such as layout, color-coding, and typography may present as similar the labels and icons of selected Web site sections

(elements that usually serve as anchors to a section's main page) in order to signal that these sections serve a common function (e.g., to present Web site content or to provide information about the Web site and its producers) and to inform a user's decision to visit some, all, or none of the sections. Understanding the meaning-making potential of the interaction between hypertextuality and multimodality, which Lemke (2002) terms "hypermodality," thus requires a multimodal perspective.

Another quality shared by many hypermedia texts is their generic complexity. For example, many Web sites for children are generically hybrid: They can be described as "edutainment" or "infotainment" because they aim to both educate/inform and entertain their overt audience (i.e., children), as well as to gain the approval of a covert audience of educators and caregivers (cf. Djonov, 2008). Alongside the relative instability of hypermedia design conventions, the ease of manipulating and combining different modes and media afforded by digital technology also contributes to the emergence of new genres alongside genres adopted from traditional media (cf. Baldry & Thibault, 2006).

Within applied linguistics, most studies of hypermedia take a corpus-based or social semiotic approach, or both. Advances in computational and corpus linguistics have inspired many quantitative studies that classify Web genres according to user perceptions of both their purpose and structure and those of their counterparts in traditional media (cf. Crowston & Williams, 2000; Dillon & Gushrowski, 2000), or index them automatically using corpus linguistic tools, formal features retrievable from the logical structure of HTML documents (e.g., number and types of hyperlinks or fonts, layout elements), or both (Mehler, Sharoff, & Santini, 2010). Among these studies, earlier ones focus on how communication on the Web, especially in organizational contexts, adopts, adapts, or departs from genres in traditional media, whereas recent ones aim to develop tools for the automatic annotation, retrieval, and computational modeling of genres that can cope with the vast amounts of information available on the Web and have wider (though mostly commercial as opposed to educational) applications. Although valuable for large-scale content analyses of Web texts, the informal genre categories and easily computable structural features employed in all these studies do not reveal how multimodal relations contribute to enabling a genre to fulfill its purpose or purposes.

A model for describing Web and other multimodal genres systematically without relying on informal genre categories is proposed by Bateman, Delin, and Henschel (2007). It involves constructing an annotated corpus of page-based documents (including Web pages) according to detailed, multilayered descriptions of the ways semiotic resources are co-deployed, and then using these descriptions to identify the genres these documents represent. Informed by advances in corpus linguistics and document design, this approach adopts the social semiotic view that "[g]enres show a collection of semiotic resources pattern together in order to fulfill recurrent, recognizable social goals" (p. 158). Albeit labor-intensive, it also allows Bateman et al. (2007) to demonstrate that the front pages of several online newspapers in 2003–4 shared less with their print counterparts than with other types of Web pages, where information is organized thematically and in terms of relevance rather than newsworthiness, and where—in line with Web technology demands—considerable space is allocated to presenting navigation options.

Halliday's (1978) theory of language as a social semiotic (systemic functional linguistics), as well as frameworks for analyzing visual design and multimodal interaction based on it (especially Kress & van Leeuwen, 2001, 2006), provide the foundation for a wide range of discourse analytic and educational research on hypermedia. Social semiotic research on hypermedia discourse includes studies that (a) explore hypermedia's meaning-making potential in general; (b) focus on specific problems and contexts of hypermedia design and/or use; or (c) present critical analyses of hypermedia texts. The first group is exemplified by Lemke's (2002) scheme for analyzing hypermedia texts. It applies to hypermedia

social semiotic theory's model of the dynamic relation between text and context. In this model, every act of communication, or text, is viewed as a configuration of three broad types of meaning: ideational—representations of experience (subject matter) and the logical relations among them; interpersonal—construals of social relations and attitudes; and textual/compositional—the interweaving of ideational and interpersonal meaning that makes a text hang together as a unit of meaning. Analyzing single Web pages, pairs of Web pages hyperlinked with each other, and short traversals of Web pages within NASA's Web site, Lemke (2002) demonstrates that social semiotic theory, due to its focus on meaning, can account for the multimodality, open-endedness, and generic complexity of hypermedia texts and explain how meaning is constructed both prospectively and retrospectively in hypertext traversals. A focus on hypermedia in general characterizes also Baldry and Thibault's (2006) method for transcribing Web pages; Martinec and van Leeuwen's (2008) framework for designing nonlinear texts by "translating" (combinations of) basic types of semantic relations into products with different interfaces and navigation structures; and Zhao's (2010) time-based model for exploring the formation of semantic relations in the unfolding of a hypermedia text.

Other social semiotic studies of hypermedia discourse are concerned with specific challenges of hypermedia design and use or with particular contexts. Using as case studies six Web sites for children and children's navigation paths through one of them, Djonov (2005, 2007, 2008) develops two tools for studying how Web site design can support or hinder user orientation: a system for describing the potential of hyperlink traversals to reveal, obscure, or transcend a Web site's textual organization; and a framework for analyzing the ideational relations that hold together information presented on and across Web pages. Stenglin and Djonov (2010) consider interpersonal aspects of user orientation in their analysis of the multimodal and hypertextual distribution of narrative elements in an educational online game for children. Focusing on interpersonal meaning in a Web-based advertising campaign, Tan (2010) theorizes the potential of hypermedia discourse to present and align users with more or less dialogic ideological positions. Through a diachronic investigation of the home pages of online newspapers, Knox (cf. 2007, 2009) demonstrates that the affordances of Web technology interact with the institutional practices of news media and give rise to new genres, such as "newsbites" (news stories consisting only of a headline, lead, and hyperlink anchor), and semiotic practices, such as the widespread use of thumbnails (small images, usually of cropped human faces, which have restricted subject matter and composition but fulfill significant interpersonal functions in individual news stories, collectively on the home page, and over time in the relationship between an online newspaper and its audience).

A social semiotic perspective characterizes also critical discourse analyses revealing how the design of hypermedia texts such as the home pages of university Web sites and other educational institutions supports certain ideological positions (cf. Lemke, 1999; Zhang & O'Halloran, *in press*).

Social semiotic research on hypermedia in education, too, has explored a wide range of issues, such as the interplay of multimodality, gender, and age in young children's interaction with e-games (Roberts, Djonov, & Torr, 2008); the incorporation of e-literature and science hypermedia in school-based teaching and learning (Jewitt, 2006; Unsworth, 2006); the use of semiotic resources, technicality, and generic stages in print-based versus electronic science texts for school and university students (Unsworth, 2004; Jones, 2007); the potential of story genres (e.g., narrative, biographical, and historical recounts) to interact with each other (Zhao, 2008) as well as with other genres (e.g., procedure, information report) (Stenglin & Djonov, 2010) in order to present engaging lessons in history and art in children's Web sites; and the value of lessons about meaning making on online newspaper homepages to TESOL classrooms (Knox, 2008).

The research overviewed here evidences the value of an applied linguistics orientation to studying hypermedia communication. It has contributed to understanding how multimodality, hypertextuality, and genre, independently and in collaboration, create meaning in hypermedia; to developing solutions to key problems in hypermedia design and use, such as user orientation, engagement, and knowledge construction; and to explaining hypermedia's role in different contexts, such as mass media and education. This research provides a solid foundation for future investigations into unexplored questions, including the interaction between searching, browsing, surfing, and generating content in hypermedia environments; the role software (e.g., HTML, Web browsers, Flash) plays in the production and use of hypermedia texts; the relations between different generations of hypermedia technologies, such as Web 1.0 and Web 2.0; actual users' traversals across hypermedia and other texts on different timescales; and how such traversals mediate the formation of identities and broader discourse practices (along the lines suggested in Norris & Jones, 2005; Lemke, 2009).

Multimodality and Identity Construction

JARRET GEENEN

Multimodality refers to a field of social science research interested in describing the ways in which multiple modes of communication or semiotic systems are used to construct recognizable meanings. Initial research endeavors sought to develop a system which would enable the analysis of visual meaning making in a fashion similar to linguistic analysis. Seminal works including O'Toole's (1994) *The Language of Displayed Art* as well as Kress and van Leeuwen's (1996) *Reading Images: The Grammar of Visual Design*, made significant contributions to our knowledge about how and in what ways visual meaning making is accomplished. Investigating visual meaning making as a social semiotic system, much of this work sought to establish a grammar with which to describe the semiotic system. Initial descriptions of visual stimuli as constructing three simultaneous, socially situated, meta-functional meanings provided incredibly important insights into the practice of social meaning making and gave impetus to what is now collectively known as the field of multimodality.

New directions in social semiotic research have emerged with particular interests invested in the analysis of moving images and real-time video-ethnographic data. At the forefront of the endeavor, Norris (2004) has developed a methodology called multimodal interaction analysis which enables the researcher to analyze real-time video data, describing the types of actions undertaken by participants using verbal and nonverbal modes of communication. Of paramount importance in Norris's research is the analysis of identity construction using multimodal interaction analysis. MIA enables the researcher to analyze video data to describe the ways in which social actors (co)produce identity through higher and lower-level actions in a particular social-time-place. Norris's research represents the most comprehensive multimodal investigation of identity construction; therefore, her methodology and particular insights will inform the bulk of discussion.

The term identity has been used in different disciplines to refer to a multiplicity of things, but for the purposes of multimodal interaction analysis, the concept of identity "includes all fully or partially (co)produced identifications, be they identifications with roles, nations or social groups" (Norris, 2011, p. 46). It has been suggested that identity is (co)produced at specific moments in time (Scollon, 1997), a process (Hall, 1996), and also a part of group practices (Wertsch, 1998). Extending these notions, identity as conceived within the framework of MIA is understood as socially (co)produced and (co-)constructed through action within an actor's specific social-time-place.

Identity is (co)produced through the performance of social actions in real time. The focus here is on the *production* of identity as instantiated in real time by social actors rather than some abstract conception of a subjective and concrete sense of self. As Norris (2011) describes,

identity is embedded and (co)produced in . . . the social-time-place of a particular social actor together with other social actors, together with and within the historical time, and together with cultural tools, and together with and within the environment. (p. 41)

2 MULTIMODALITY AND IDENTITY CONSTRUCTION

Identity is produced in real time by social actors acting within their social networks. Through the orchestration of multiple communicative modes, social actors produce their identities through various forms of social action. Identity is perceivable through action and all action is telling of one's identity. Since identity is continuously produced and instantiated in real time, the concept of identity element is used in reference to the specific identifications that are produced.

The term *identity element* is used to describe particular identifications instantiated in social action because, within the framework of MIA, identity is understood as a process rather than a being and it is constantly developing as well as changing (Norris, 2011, p. 40). In other words, identity elements range on a continuum of permanence because some identity elements, such as a national identity element, are relatively stable and persistent, whereas, a work identity element may be less stable and persistent. In everyday interaction, participants (co)produce particular identity elements through various higher, lower, and frozen actions. These identity elements are of heuristic value and are not distinct categories. They range on a scale of permanence and can also be generally classified as role linked, nation linked and group linked.

Social actors (co)produce identity elements through higher, lower, and frozen actions, with other social actors, in a specific social-time-place. These identity elements, which are realized through identity-telling actions (e.g., cooking of a meal for one's children may tell of a parental identity element), range on a continuum of stability and culminate to influence the perception of one's person identity (outlined below). Thus, identity (co)production is a continual process wherein particular identifications may be newly instantiated and others may be discarded depending on the social-time-place including historical and contextual affordances. Another important component of identity construction is the phenomena wherein a social actor can and often does produce more than one identity element at a time. It is typical for a social actor to "produce several identity elements on different levels of attention/awareness" (Norris, 2011, p. 114) through multiple communicative modes.

The notion of foreground-background continuum has been used to describe the ways in which awareness and attention are employed at differing levels by a social actor within a site of engagement. The site of engagement can best be described as:

the real-time window opened through the intersection of social practice(s) and meditational means that makes that lower (or higher) level action the focal point of attention of the relevant participants, and radiates from there encompassing the intersection of practices and meditational means that make those lower or higher-level actions the less focused or un-focused points of attention of the relevant participants. (Norris, 2011, p. 59)

Any particular site of engagement encompasses the primary focal point of the interaction which is described as the foreground, the background which comprises activity less attended to by the actors and all varying degrees in the middle. Using the notions of foreground-background continuum and site of engagement, we are able to see how different levels of attention and awareness situate actions on the continuum, making possible the production of multiple identity elements at the same time. In other words, social actors may engage in multiple actions at different levels of the foreground-background continuum, and these actions may produce different identity elements simultaneously. An example might be a case of an actor playing a musical instrument while also minding their child who is occupied with toys nearby. The actor may be simultaneously producing a musician identity element and a parent identity element at different levels of the continuum instantiated by varying levels of attention and awareness.

Discussion about the phenomenological production of identity must include an explication about the perception of identity elements by other social actors through the concept

of modal density. Identity elements, which may be produced inadvertently through higher-level actions by a social actor, are acutely perceivable by other interlocutors and this may be attributed to high modal density. Here, modal density refers to “the perceivably produced higher-level action and with it the perceivably produced identity element” (Norris, 2011, p. 116). Modal density can range on a scale from high to low and negatively correlates with the level of attention/awareness given to a particular action. In other words, actions constructed in the mid-ground or background of one’s attention/awareness, are typically constructed with less modal density than those in the foreground.

High modal density can come about through three primary ways: through the intensity of mode, through the complexity of modes and through simultaneous intensity and complexity of modes. Intensity of mode refers to the strength with which a particular mode takes on primacy or is dominant in a particular action. Modal complexity is a term used to describe the utilization of multiple modes in the execution of a higher-level action. And, the third way modal density is realized is through the combination of both wherein multiple modes are complexly interlinked and foregrounded in one’s attention/awareness. Thus, identity elements can be produced with high, medium, or low modal density depending on the utilization of communicative modes and are produced along a continuum of attention/awareness; both affect the strength with which an identity element is perceived. Social actors can not only produce multiple identity elements simultaneously; individual identity elements can be emphasized through instantiation in multiple layers of discourse. This is called vertical identity production.

While identity elements are produced through manual actions undertaken by an individual, identity can also be produced through layers of discourse. Within the framework of MIA, there are three particular layers of discourse which function in the production of identity: *outer layers of discourse*, *intermediary levels of discourse* and *central layers of discourse*. As Norris (2011) points out,

these three layers of discourse are viewed in multimodal interaction analysis as building three vertical layers of an identity element; and vertical identity element production is apparent in the levels of discourse that a social actor refers to and/or enacts simultaneously. (p. 220)

Outer layers of discourse, which refer to those discourses that are formed by society and enforced by the extended networks and institutions a social actor engages with, produce a *general* identity element. Intermediary layers of discourse formed with and through social networks, both immediate and extended, produce *continuous* identity elements. Central layers of discourse formed through the engagement in immediate actions produce *immediate* identity elements. The vertical (co)production of a particular identity element through three difference layers of discourse functions to emphasize that particular element. In other words, the instantiation of a particular identification in multiple layers of discourse strengthens the phenomenological nature of the identity element. The strengthening and multiple (co)production of a particular identity element may contribute to stabilization in identity production and thereby, person identity production.

It is important to distinguish between the micro identity elements that individuals (co)produce moment to moment and the idea of person identity which refers to one’s overall way of being and acting in a social world. The concept of person identity relates to the more stabilized traits, characteristics, and identifications of a particular social actor as they are regularly and consistently (co)produced within their various social networks. Essentially,

person identity production encompasses the notion of national identity as it is produced by social actors in their life world, and the notion of role when social actors identify with the roles they enact . . . [it] entails all identity elements . . . person identity is a social actor's overall perceivable identity. (Norris, 2011, p. 319)

Paramount is the fact that person identity, while referring in a more holistic fashion to a social actor's overall psychological and sociological makeup, is instantiated in the micro identity-telling moment to moment unstable actions that occur in a specific social-time-place. As Lemke (2008) points out, "the longer term aspects of our identity are not determined by a single performance. They constitute patterns across time, across situations, even across clusters of situation types" (p. 24). Thus, one's more stabilized person identity is perceivable as a result of recurrent and continually produced identity-telling actions across situations and time.

As explained, current developments in multimodality and identity construction take identity to be perceivable through socially situated actions within a particular actor's social-time-space. Identity is (co)produced and (co)constructed in the form of identity elements, moment to moment in real-time interaction. Social actors are capable of (co)producing multiple identity elements simultaneously in and through their social networks and specific identity elements can be emphasized through instantiation in multiple discourse layers. The recurrent and continuous (co)production of particular identity elements over time can contribute to the production of a more stabilized person identity. However, identity is continuously and fluidly changing all the time, which is why we are particularly concerned with the production of identity through interaction, moment to moment, in its vast complexity.

Multimodality and Literacy

MARK EVAN NELSON

“Multimodality”—literally, the quality of integrating multiple forms or means—is a term that has been taken up by a number of fields over the past few decades (e.g., in medicine) to describe the co-application of a diversity of diagnostic imaging strategies, and in research into artificial intelligence, virtual reality, and augmented reality to talk about coordinated aspects of multisensory experience within digital environments. In the field of language and literacy studies, however, “multimodal” has come particularly to describe communication that features the simultaneous, sequential, or comparative presentation of two or more means by which meanings may be conveyed. These discrete communicational means, or “semiotic modes,” are typically diverse in form and may include, for example, spoken language(s), written script(s), static imagery, moving (e.g., filmic or animated) imagery, and music. In further defining terms, there is an important distinction to be made between the concepts of semiotic mode and medium, which are often confused and conflated. Jewitt helpfully explains the difference:

Medium refers to technologies of dissemination, such as printed book, CD Rom, or computer application. Mode refers to any organized, regular means of representation and communication, such as still image, gesture, posture, speech, music, writing, or new configurations of the elements of these. (2004, p. 184)

Multimodality and a Social Semiotic View of Meaning

According to the formal distinctiveness of semiotic modes, it is also generally understood that each semiotic mode is inherently disposed to offering particular kinds of opportunities and parameters (most often discussed as “affordances” and “constraints,” respectively; see Kress & van Leeuwen, 1996/2006; Kress, 2000, 2003) for the construction, the *making*, of meaning. Simply put, each mode seems naturally better suited for conveying certain kinds of meanings over others. Illustrating this notion, linguist and educationalist Gunther Kress (2003, 2010), perhaps the most influential and earliest promulgator of the construct of multimodality in the language and literacy field, offers the example of the representation of a plant cell in a science classroom. Kress relates a scenario in which students are asked to “explain” a plant cell and its nucleus through the use of both linguistic and visual (pictorial) representations. In each case, Kress argues, the students are required to make different kinds of representational decisions. In the case of the linguistic explanation, Kress writes, students are most likely to opt for something like “the plant cell has a nucleus,” which semantically establishes “a relation of possession” through the sequential ordering of “cell” and “nucleus” and the use of a form of the verb “to have,” which syntactically links possessor and possession, typically. In drawing, by contrast, the students must make other kinds of decisions, such as to the placement, shape, or size, of the nucleus within the cell (2010, pp. 16–17). These differences make manifest particular aspects of the semiotic organizing “logic” that characterizes each mode: a dominant sequential organization in language and a spatial one in the image.

Figure 1 Midday traffic in Hanoi's Old City © Mark Evan Nelson

Here it is important to stress, as Kress also does, that the meaning-making dispositions that attend different modes do not absolutely determine the kinds of meanings that a mode in communicative use might convey. For example, with regard to the photograph of "Midday Traffic in Hanoi's Old City," shown in Figure 1, a brief written description of this image, a sentence or two, could not convey to the reader the specificity and richness of detail (the tones, forms, facial expressions, etc.) that she would get from viewing the photo itself. However, a more comprehensive and carefully worded description would likely do a better job of getting the particularities across, of *evoking the image* so to say, than would the sparer caption. In this way a designful approach is taken, ingenuity is brought to bear, in the service of further activating the semiotic potentials of written language.

Still, the affordances and constraints of different modes when considered in the abstract can only partly account for multimodal meaning-making. In real, socially embedded instances of communicative practice, all "resources" for representation and communication, all modes included, have histories of use and fulfill particular, conventional expressive functions. These material and conceptual resources (e.g., languages, paintbrushes, knowledge of genres and other stylistic structures) are employed in the ways that they are based on the kinds of communication they are perceived as able to support, and these perceptions are largely attributable to social experience. Thus, communication, in both receptive and productive instantiations, which Kress and van Leeuwen (2001, p. 8) call "articulation" and "interpretation," respectively, is fundamentally a social project, involving the coordination and co-deployment of multiple meaning-making resources, which may be expressed in a range of semiotic modes.

The picture of communication sketched so far evinces a distinctly "social semiotic" bent, grounded in the work of linguist M. A. K. Halliday and elaborated by his followers (e.g., Halliday, 1985; Hodge & Kress, 1988; van Leeuwen, 2005). The terms "functional grammar"

and “systemic-functional linguistics” (SFL) categorically denote this body of theoretical and empirical work. In his groundbreaking volume *Language as Social Semiotic* (1978), Halliday proposes that language can only be understood “in the total context of the interaction between an individual and his human environment” (p. 9), that is, in socially embedded contexts of functional use. According to a social semiotic view, then, meaning is effectively bifurcated into potential and actual states, where potential meaning describes the range of possible meanings that can be made in a given text or other instance of communication and actual meaning is the particular significance that is “actualized” against the field of all other possibilities within a specific social context and in light of the purposes of the meaning maker. This stands in contrast to also highly influential notions of the universal, innate nature of meaning in language, most notably associated with linguist Noam Chomsky (1965) and the theoretical program originally called “transformational-generative grammar” (TGG), which Chomsky and colleagues formulated and have developed over the past half-century. While TGG and succeeding theories take form as their starting point in understanding language, social semiotics begins with meaning, which in each case “if carried through consistently . . . ends up with a strikingly different kind of description of language” (Thompson, 2004, p. 2).

This primary concern for meaning and function within social semiotics brings with it the vital recognition that language is not part and parcel of communication itself; though it is undeniable that language is a critically important resource for communication, it cannot be considered the only resource, perhaps not even the principal one. Rather, the meaning maker always selects from among the available range of resources for communication—language being one, but also including images, gestures, sounds, and even silence (Stein, 2007)—based on individual and conventional perceptions of what Kress (2003) calls “fitness for purpose” or “aptness” for realizing an expressive intention, which follows on the discussion above. This is the crux of what is described as multimodal literacy: the adaptive capacity to recognize, imagine, and effectively exploit the meaning-making potentials of a diverse array of resources in view of one’s own purposes for communication.

Multimodality, Literacy, and Literacies

Having established a theoretical basis for a multimodal view of communication and literacy, it is appropriate next to address the crucial question of what importance or relevance this view may hold for learning, and life, in the 21st century. What justification could there be for complicating tidier definitions of literacy-as-reading-and-writing with the notion of multimodality? Why and how is it that this view should influence the ways in which communication is approached, learned, and taught?

First, to rehearse what may be obvious to some, while language is not part and parcel of communication itself, multimodality certainly seems to be. In even the most casual, workaday instances of face-to-face communication, for instance, we draw upon gesture, gaze, proxemics, touch, and smell, among others in the panoply of sensory, experiential, and conventional resources that are marshaled for meaning-making purposes. Moreover, as anthropologist Ruth Finnegan (2002, p. 225) writes, though “this multiplicity is something we draw on every day . . . taking it for granted, we seldom notice it consciously.” To this extent, communication always has been and cannot but be multimodal.

This does not mean, however, that communication has not changed or is not changing; radical changes in the landscape of literacy have occurred and are still afoot. An unmistakable, fundamental transformation has taken place in the quantity, variety, and complexity of texts that constantly confront so many of us, owing principally to the existence and use of computers and the Internet. More to the present point, the kinds of texts so many of us

4 MULTIMODALITY AND LITERACY

now typically encounter and increasingly have occasion to create are, as a matter of comparative degree, definitively multimodal, for example, so-called “social media,” like the wildly popular Facebook, which may integrate images, written text, graphics, sound, etc., in a variety of arrangements on a single “page.” So, much interest in multimodal literacy is focused especially on the preponderant and increasing diversity of modes and media that comprise everyday texts—digitally constituted texts in particular—and the social and educational implications of this diversity.

The best known and most influential scholarly effort to come to terms with these new demands placed on literacy and literacy pedagogy arose out of a meeting in 1994 in New London, New Hampshire of ten prominent scholars from Australia, the United Kingdom, and North America and representing a variety of social science fields, but with a common concern for problems of education. These scholars were especially concerned with what they perceived to be grave disparities in educational outcomes and future opportunities among the world’s people. The group included Professors Courtney Cazden, Bill Cope, Norman Fairclough, James Gee, Mary Kalantzis, Gunther Kress, Alan Luke, Carmen Luke, Sarah Michaels, and Martin Nakata, who collectively became known as the “New London Group.” The New London Group first published a unified presentation of their ideas in 1996 in the *Harvard Educational Review*, in the form of an article-length manifesto entitled “A Pedagogy of Multi-Literacies: Designing Social Futures.” In this paper, the authors take the position that the essential purpose of education “is to ensure that all students benefit from learning in ways that allow them to participate fully in public, community, and economic life” and that “[l]iteracy pedagogy is expected to play a particularly important role in fulfilling this mission” (New London Group, 1996, p. 60). The New London Group go on to argue that a literacy pedagogy appropriate for and facilitative of the achievement of “full and equitable social participation” needs critically to accommodate the literacy needs brought about by two principal trends toward increased plurality and diversity in the global community:

First, we want to extend the idea and scope of literacy pedagogy to account for the context of our culturally and linguistically diverse and increasingly globalized societies, for the multifarious cultures that interrelate and the plurality of texts that circulate. Second, we argue that literacy pedagogy now must account for the burgeoning variety of text forms associated with information and multimedia technologies. This includes understanding and competent control of representational forms that are becoming increasingly significant in the overall communications environment, such as visual images and their relationship to the written word—for instance, visual design in desktop publishing or the interface of visual and linguistic meaning in multimedia. (New London Group, 1996, p. 61)

This second point speaks directly to the presence and importance of multimodality in the texts and literacy practices of the present and the presumable future. Still, these aspects of multiplicity within texts and without them, that is, in sociocultural contexts of literacy, are fundamentally and inextricably interrelated, as, in the New London Group’s phrase, “the proliferation of communications channels and media supports and extends cultural and subcultural diversity” (p. 61). The pedagogical program devised by the New London Group to address the interaction of these trends and their implications has been termed “multiliteracies.”

The operative principle and central practical process of multiliteracies is “design.” Design is the name given to the adaptive meaning-making capacity described above and is, in a limited sense, a replacement term for both “reading” and “writing” and the roles these play within the traditional discourse of literacy. Whereas reading and writing may invoke notions of the decoding and encoding of assumedly fixed meanings on the sole basis of

linguistic scripts, “design asks what is needed now, in this one situation, with this configuration of purposes, aims, audience, *and with these resources*, and given *my* interests in this situation” (Kress, 2003, p. 49, emphasis in original). Design is expressly meaning-oriented, not language-oriented, entailing the selection and coordination of the whole range of semiotic modes as befits specific communication needs. The notion of *designing meaning*, then, necessarily reforms and refocuses conceptions of literacy and learning in a number of highly significant ways; and multimodality is deeply implicated in these changes.

A core presupposition of multimodal literacies (or multimodal meaning design) within the broader framework of multiliteracies is that meaning is constructed both in and between different semiotic modes. In traditional conceptions of literacy, there is a tendency to regard meaning as residing within written or printed text, notwithstanding the interpretive work that must be done to access this meaning. A literacy that mobilizes a diversity of resources toward building meaning *in the moment*, however, is an essentially relational one. This is to say, the meaning potential resides as much in the interstices between the pictures, elements of language, spatial arrangements of features, etc., in a given text as within these—maybe more so. (Again, too, these potentials are founded in personal and social experience.) When we “read” a page on the World Wide Web, for instance, we attend not only to titles, banners, and other written-language texts, but also to color choices, graphics, photos, spatial arrangements, sounds, etc., as the case may be. And though we may actualize different, even dissonant meanings in the various “design elements,” we interpret these dissimilar elements as both text and co-text, forming integrative impressions of meaning relationships among the parts and of the whole. Reflexively, too, these multimodal juxtapositions help us to see and understand the meaning potentials of the individual component resources in new ways. Herein, according to Kress, lies the capacity for learning and creativity within multimodal literacy practices, a process he calls “synaesthesia.”

Synaesthesia, as it is understood here, entails the psychological cooperation of “transduction,” which is the shifting of “semiotic material,” the stuff of meaning, across boundaries of mode and medium, and “transformation,” the qualitative reshaping of the meanings made in individual modes that results from transduction (Kress, 2003, p. 36). The *psychological redesigns* can and do bring about the redesigning of material resources too as the potential significances and uses of these are synaesthetically reimagined. This notion also resonates, perhaps, with Lemke’s (2005) theory of “transmedia traversals,” which aims to account for the “ecosocial” meaning-making implications of crossing boundaries of genre, media, and context.

Such theoretical frameworks have very helpfully pointed the way for others whose work aims for tangible, practical understandings of multimodal literacies and learning; but there are many important questions still to be answered. What does multimodal creativity and learning look like *on the ground* and how does it happen when it does? When it doesn’t come about, what is the explanation for that? What particular kinds of capacities and knowledge characterize the multimodally literate, and how can these be learned, developed, and taught? What roles do culture and social life play in these learning processes and practices? These questions have been addressed by Nelson (2006, 2008), for instance, in qualitative studies of the multimodal literacy practice of digital storytelling in Japan and the USA. On the basis of documentation and analysis of the creative decision-making processes of adult English-language learners involved in composing personal narratives in multimedia form, Nelson specifically identifies and illustrates a number of cases of multimodal design (as articulation) in which the expressive intention of the multimedia author was obscured, altered, or amplified in different ways, as a function of the semiotic affordances and constraints of different modes and the degree of the authors’ understanding of and control over these. More, Stein (2007), in the context of an examination of “multimodal pedagogies” in a township of Johannesburg, South Africa, presents a highly

nuanced analysis of a narrative produced by a young Zulu-speaking girl in three distinct forms: a spoken performance, a written story, and a drawing. Stein shows how meaning-making orientations, such as toward the body and the audience, change as the story is “transduced” from speech to writing to pictures, clearly and concretely demonstrating the aforementioned creative capacity of synaesthesia and the pedagogical potential afforded by a multiliteracies approach. Still, too, other research into multiliteracies and accordant multimodal pedagogies has highlighted serious social and ideological constraints, such as in the marginalization of non-traditional literacy practices in mainstream educational settings in Australia, reported by Tan and McWilliam (2009). These researchers found that in each of two quite different settings—a well-resourced, high-performing senior school and a “reception” school for at-risk migrant English-language learners—meaningful digital literacies work was sidelined and subordinated to traditional print literacy-based activities, which were deemed more fundamental, substantial, and consequential.

Understandings of multimodal literacies continue to take shape and their significance is ever clearer. As billions of people depend more and more on multimedia technologies in the performance of seemingly all aspects of personal, social, and professional life, and, as Kress (2003) notes, the texture of our world shifts toward the image and the screen and away from printed word and book, multimodality and literacy beg urgently to be reconciled.

Multimodality and Metaphors

MICHELLE M. LAZAR

Introduction

Metaphors are commonly viewed as a figurative literary device that adds eloquence to a speech or text. The assumptions underlying this popular understanding of metaphors are that they are a property of words; they are used to achieve some artistic or rhetorical effect; they are based on a relationship of similarity between two entities; they are a conscious and skilled use of language; and they are a figure of speech whose function is merely decorative (Kovecses, 2002, p. vii). Challenging the above understanding is the *cognitive linguistic view of metaphors*, first developed in the work of George Lakoff and Mark Johnson (2003/1980). According to this view, metaphors are a property not of words but of concepts; are not just used for aesthetic purpose but enable the understanding of particular concepts and ideas; are often not based on the resemblance between entities; are used effortlessly and often unconsciously by everyone; and are an inevitable process of human thought and everyday human communication (Kovecses, 2002, p. viii).

The view adopted in this entry is based on the cognitive linguistic approach that maintains the conceptual nature of metaphors; hence the term “conceptual metaphors.” In what follows, the theory of conceptual metaphors is first outlined. Two successive sections will then deal with the expression of metaphors in language (verbal) and in other signifying systems (nonverbal), distinguishing between monomodal and multimodal expressions of metaphor, as well as showing the operation of multimodal metaphors, respectively. The penultimate section considers some challenges posed to the conceptual metaphor theory (CMT) by scholars working on nonverbal and multimodal metaphors. The entry concludes with some suggestions for further research on multimodal metaphors.

Conceptual Metaphor Theory

In the cognitive linguistic approach, metaphors are conceptual in nature, in that we understand one conceptual domain in terms of another conceptual domain. (A “conceptual domain” refers to “any coherent organization of experience”; Kovecses, 2002, p. 4). Let us take the example *LIFE IS A JOURNEY*. Here, the conceptual domain of life is understood in relation to another conceptual domain—that of a journey. *LIFE* is what is called the “target domain,” which is the conceptual domain that we need to understand, whereas *A JOURNEY* is referred to as the “source domain,” that is, the conceptual domain we draw upon to make sense of the former. Typically, in CMT, the target is a more abstract concept that is comprehended via the source, which is a more concrete concept, and the qualities of abstract and concrete for target and source, respectively, are usually not reversible. The rationale for this is based on the assumption that “our experiences with the physical world serve as a natural and logical foundation” for making sense of more abstract domains (Kovecses, 2002, p. 6). Abstract conceptual domains such as life, arguments, theories, and ideas figure as target domains, whereas perceptually more physical/concrete conceptual domains such as journeys, wars, buildings, and food figure as their source domain counterparts, respectively (Lakoff & Johnson 2003/1980).

DOI: 10.1002/9781405198431.wbeal0829

The process by which metaphoric comprehension is achieved is called “mapping,” whereby elements of the source domain are mapped or transferred onto the target domain, usually systematically and unconsciously. In the case of the *LIFE IS A JOURNEY* metaphor, identifiable features of a journey (such as beginnings, ends, detours, and so forth) get mapped onto the domain of life, so that the latter comes to resemble the former. A conceptual metaphor not only enables the understanding of a more abstract domain but also, importantly, mediates and structures it (Kovecses, 2002; Knowles & Moon, 2006). In other words, the domain of life assumes the quality of a journey (or “becomes” a journey) through the mapping process.

Further, Fauconnier and Turner (2002) have identified another process, termed “blending,” in which two or more (instead of singular) input spaces are involved in metaphoric comprehension. For example, in a print advertisement for a music radio station, the caption that reads “Make space for today’s hottest hits” is visually accompanied by a picture of two DJs dressed as doctors in white lab coats (*Straits Times*, January 12, 2011). One holds up a medical instrument to a listener’s ear to check on wax buildup, while another holds up a hand-held vacuum cleaner with its nozzle in the listener’s ear. “Making space” is here understood in terms of a blend of two conceptual domains—one from a medical domain of checking ear-blockage and another from a “lifeworld” domain of cleaning.

In CMT, a conceptual metaphor is worded in the form of a statement *x* IS *y* (thus, *LIFE IS A JOURNEY*), rendered in small capital letters. The use of small capitals indicates that the statement does not refer to the actual wording found in the discourse; instead, it is the underlying conceptualization identified from, as well as made manifest in, such metaphoric linguistic expressions as “Mary is at the crossroads of her life,” “Death signals the end of the road,” and “Jim lost his way during his youth, but got back on track in his later years.” A conceptual metaphor may be manifested in bits of discourse (as in the sentences above), or structure texts in entirety. Knowles and Moon (2006, p. 42) have noted that *LIFE IS A JOURNEY*, in fact, has framed whole texts, from song lyrics (e.g. the Beatles’ “Long and Winding Road,” Lynyrd Skynyrd’s “Freebird,” and Joni Mitchell’s “Woodstock”) to books and plays (e.g. Cervantes’s *Don Quixote*, Tolkien’s *Lord of the Rings*, and Beckett’s *Waiting for Godot*).

Verbal and Nonverbal, Monomodal and Multimodal Metaphors

The linguistic, or the verbal, is the most familiar mode of metaphoric expression. However, if metaphors are a conceptual phenomenon, it then follows that metaphors can be expressed through nonverbal modes as well. As Lakoff and Johnson (2003/1980, p. 3) noted, “metaphor is pervasive in everyday life, not just in language but in thought and action.”

Over the years, the pictorial or visual mode has been the most popularly researched nonverbal metaphor. Kovecses (2002, p. 58) provides an example of a visual metaphor from the Walt Disney film *The Hunchback of Notre Dame*. The cruel judge of Paris has an uncontrollable sexual desire for Esmeralda, the beautiful gypsy girl, and in one scene, the entire room and palace are consumed in flames. Kovecses explains that the metaphor that is given visual expression here is *SEXUAL DESIRE IS FIRE*, where the flames correspond to the judge’s intense sexual desire.

More recently, studies have begun to investigate other nonverbal modes of metaphoric expression. For instance, Knowles and Moon (2006, p. 142) offer an example from the field of electro-acoustic music, where sounds are used to realize concepts. Knowles and Moon cite a composer’s (Jonty Harrison’s) description of one of the principal source sounds derived from children’s balloons for his piece *Hot Air* as follows:

[The balloons] “give rise to a train of thought which, after linking ‘toy’ balloons to ‘hot air’ balloons, went on to draw in other concepts of air (breath, utterance, and natural phenomena) and heat (energy, action, danger)” (Harrison 2002). These concepts are realized by “a shift of focus away from instrumental generalizations” to compositions where “the musical forms are no longer abstract, but abstracted from . . . recognizable sounds. The sounds of our every day experience” (Harrison 1996: 16). The result of the synthesized sonic composition *Hot Air* was . . . to reveal “another, altogether more worrying image: that of the inflated balloon as a metaphor of the very environment of the Earth itself” (Harrison 2002).

Regardless of whether it is verbal or nonverbal, if one mode is solely used for metaphoric expression (as in the examples above), then that is called a monomodal metaphor. Unlike monomodal metaphors, multimodal metaphors, as defined by Forceville (2009a), are those whose target and source domains are predominantly or entirely presented in different modes, which may include visuals, written language, spoken language, gestures, non-verbal sound, and music. According to this definition, verbo-pictorial metaphors count as multimodal metaphors, but so do verbal metaphors whose target and source are presented in, say, written and spoken modes, respectively (Forceville, 2009b, p. 383).

Multimodal Expressions of Metaphor

In this section, three examples of multimodal metaphors are presented that show various combinations of modes in operation: written language/visuals; spoken language/gestures; and visual/music.

An example of a metaphor expressed through the co-deployment of language and image comes from a set of print advertisements on female beautification (Lazar, 2009). One of the metaphors identified in the study is *WOMEN’S BODIES ARE BATTLEFIELDS*, which is realized through language (for example, “To fight the signs of time from appearing on her face,” and “targeting on localized fat and cellulite areas”), and visual representations of cross-hairs superimposed on parts of women’s bodies. Lazar notes that the circular outlines of cross-hairs are metonymic both for the weapon directed at the particular sites and for the invisible sniper whose gaze is fixed upon the targeted zones. Through this metaphor, women’s bodies are treated as a territory of surveillance and militarized action.

Muller and Cienki (2009) have studied verbo-gestural metaphors in face-to-face communication. For example, in one case, a young German woman describes how her teenage love became increasingly “clingy,” which gets expressed through the collaboration of a hand gesture and language:

- (1) [Muller & Cienki (2009, p. 307); G1; transcript partly reproduced]
 open palms touching each other repeatedly
also da hab ich schon gemerkt naja'
 So there I had already realized, well,
des is ganz schon klebrig.
 this is pretty clingy.

Muller and Cienki note that the source domain of “clingyness” to describe the relationship is here expressed verbally and gesturally. They observe that the speaker’s open palms repeatedly touch each other, move apart, and then “stick” back together, as though the palms were sticky and hard to separate. “Clingyness” is here enacted by the hand gesture even before the verbal part of the metaphor is expressed.

In multimodal expressions of metaphor, the verbal is usually one of the modes involved (as in the examples above); however, this is not always or necessarily the case. In the next example, from a television commercial (Forceville, 2009b), visuals and nonverbal sounds combine to realize a metaphor. The commercial is for an Iglo instant meal, in which a mini-corncob and a French bean are visually personified as walking toward an Iglo package. The conceptual metaphor in operation, identified by Forceville, more specifically is CORNCOB AND FRENCH BEAN ARE BRIDE AND GROOM, based on the tune of the Wedding March accompanying the personified image, which metaphorizes the two vegetables as bride and groom. Forceville notes that if the sound were turned off, most viewers would not be able to access the source domain on the basis of the visual cues alone.

Some Challenges to CMT

While drawing upon classic CMT, nonverbal and multimodal metaphor research has raised some cautionary points about it. For one, although CMT maintains that metaphors rely on the conceptualization of the abstract vis-à-vis the concrete, in the case of nonverbal and multimodal metaphors, the target and source may both be concrete. This is quite common in consumer advertising, where the target domain is typically the product, which is depicted, and so is necessarily concrete; however, it can be found elsewhere, too, such as in political cartoons and in characterizations in films (Forceville & Urios-Aparisi, 2009).

Another challenge is posed by the need to verbalize the underlying metaphorical conceptualization in the *x is y* format. While it has been noted that the naming of conceptual metaphors in this way can never be a neutral undertaking—rather, it relies on the analyst’s interpretation of the observed metaphoric expressions—the subjective element involved is exacerbated in the case of multimodal metaphors, where the source domain is expressed nonverbally. For example, in the branding of a company, Koller (2009, p. 48) notes that a company’s business principles might feature pictures of a boat race with no possible literal interpretation. Such an image opens up a number of different ways of wording the metaphor, such as *COMPANY X IS A RACING TEAM*, or in more general terms, *BUSINESS IS A RACE*. In view of this complexity, she suggests that the traditional *x is y* format is limiting; instead, inferred metaphors ought to be seen as part of what Musolff (2006) has termed a “metaphor scenario,” which can accommodate different levels of abstraction. This would work especially for multimodal metaphors, which tend to be less explicit than purely verbal ones (Forceville, 2009b).

Conclusion

In concluding, we shall consider areas for further research. In terms of genre, with the extension of research into nonverbal and multimodal metaphors, many genres other than purely written ones have opened up for study, including advertisements (Forceville, 1998), cartoons (El Refaie, 2003; Shinohara & Matsunaka, 2009), spoken interaction (Cienki, 1998), film (Carroll, 1996; Kovecses, 2002), music (Forceville, 2009b), and design (Caballero, 2003). It becomes worthwhile to investigate how genre may affect the production and interpretation of metaphors. Forceville (2009a) has noted that advertisements, for instance, quite neatly fit the *TARGET IS SOURCE* format, where the target typically coincides with the promoted product or brand, and that the features mapped from the source to the target are predictably positive. However, metaphors in more artistic contexts may be less straightforward, and could allow for greater freedom of interpretation.

Cross-cultural production and interpretation of metaphors is another area in need of greater research. Pictorial and multimodal metaphors, according to Forceville (2008), have

greater cross-cultural access as they are more easily recognized transnationally than those linguistically expressed. Yet we cannot assume that nonverbal and multimodal metaphors will be interpreted in the same way across cultures. It is worth investigating what areas in the conceptualization and expression of metaphors remain constant and what varies across cultures (Kovecses, 2005).

Finally, although in recent years metaphor scholars have begun to focus on multimodal expression of metaphors, few studies have been truly multimodal. Much existing research on multimodal metaphors tends toward bimodality (involving two modes) rather than multimodality (involving more than two modes). As the multimodal “turn” in metaphor studies establishes itself, we can expect more research on conceptual mappings and blends that involve the interplay of a plurality of modes.

Multimodality and Rhythm

THEO VAN LEEUWEN

The Importance of Rhythm

Rhythm plays a crucial role in creating cohesion and meaningful structure in multimodal texts and communicative events that unfold over time. Edward Hall (1983) has vividly described just how finely people attune their speech and body rhythms in everyday interaction, and the close analysis of extracts from films (Van Leeuwen, 1985; Martinec, 2000) has uncovered the subtle interaction of the rhythms of actors' movements, dialogue, and music with the rhythms of camera movements and editing.

The rhythmic structure of multimodal texts has its basis in the rhythms of our body—the heartbeat and the breathing cycle. Poststructuralists, in a psychoanalytic vein, have at times described linguistic and semiotic codes as harnessing and taming the pleasures of the body, but in fact the two are closely intertwined. Understanding body rhythm and the physicalities of motor behavior is fundamental to understanding semiotic structuring and multimodal communication. In semiosis, as Kristeva has put it (1980, p. 173), “instinctual rhythm becomes logical rhythm.”

It is regrettable that rhythm, so far, has not yet achieved a more central place in multimodal text analysis and multimodal conversation analysis, because rhythm is the one thing all time-based semiotic modes have in common, and rhythmic structure is therefore the single most important factor in integrating different time-based modes into a multimodal whole, and therefore in understanding multimodality. As Couper-Kühlen (1993, p. 112) has said, in a linguistic account of rhythm: “The principles of organization of [speech, verse and music] are surprisingly similar, and allow for the same play off between abstract construct or underlying structure and actual realization.”

As is appropriate in multimodal analysis, multimodal theories of rhythm draw on a multidisciplinary range of references, including linguistics (e.g., Halliday, 1967, 1970; Couper-Kühlen, 1993), nonverbal communication (e.g., Hall, 1983), literary theory (e.g., Leech, 1969), and musicology (e.g., Cooper & Meyer, 1960). The two main approaches to rhythm in the multimodality literature are those of Van Leeuwen (1985, 1999, 2005) and Martinec (1996, 2000, 2002). The theory of rhythm is also taken up in Baldry and Thibault's (2006) compendium of multimodal transcription and analysis. The account below integrates these fundamentally compatible accounts, pointing out differences where appropriate.

Rhythmic Feet in Speech, Music, and Action

The essence of rhythm is regular alternation—alternation between an up and a down, a tense and a lax, a long and a short, a loud and a soft, and so on. Such alternation is so essential to human perception that we perceive it even when “objectively” it is not there. Experimental phonetics has shown that, when listening to a series of absolutely identical, evenly spaced click noises, people will, at regular intervals, hear one of the clicks as accented, as more salient than the others (Allen, 1975), and the intervals between accents will be heard as equally long, as “isochronous,” even when in reality they are not quite

2 MULTIMODALITY AND RHYTHM

equal (Lehiste, 1970). These accents then demarcate “rhythmic feet,” units consisting of an accented syllable plus or minus one or more unaccented syllables, with the accented syllable higher in pitch, louder, or longer, or some combination of these. The principle can also be applied to music or sound effects, or to movements, where an accented gesture or other movement may be more salient because of its greater force or extent, its “vividness,” as cognitive psychologists say (cf, Martinec, 2000, p. 291).

Tempo then results from the duration of these rhythmic feet. Musical tempo, judging by the metronome, ranges from 40 to 208 pulses per minute—the human heartbeat ranges from about 50 to 200 pulses. Ninety pulses per minute is not only a medium tempo for music, but also the average rate of easily paced walking in adults (the musical term *andante* means “walking,” and jazz musicians speak of a “walking bass”).

Rhythmic accents play a key role in articulating meaning because they foreground the sounds or movements that carry the key information of each rhythmic foot (in the example below, the rhythmic feet are separated by oblique strokes and the accents are underlined):

/Why do you/ think I am/ working like/ this/

It is clear that the meaning of this line might still come across if we just heard *Why think work this?* but not if we only heard *do you I am king like*. The same analysis can be applied to musical accenting, or to accenting movements. Figure 1 shows the opening motif of Tchaikovsky’s fifth symphony. The accented notes are crucial in getting the musical message across. The first accent falls on a “minor third,” the note that causes the melody to be in a minor key, hence “sad.” The second accent rises up from this, but only a little, as if some kind of musical gravity is holding it back. The third accent then lapses back again, so that the melody, literally and figuratively does not “soar.” In the opening line of “Joy Spring,” a jazz composition by Clifford Brown (see Figure 2), it is quite different. The tune starts by joyfully rising in pitch, in big leaps.

The example below, which represents somebody repeatedly and insistently knocking on a door, contains two “silent beats” (Couper-Kühlen, 1993): The timing of the wait between the door knocks continues the regular beat (ONE/two/three/ONE/two three) set up by the pattern of the knocking, and the pulses in these rhythmic feet are felt rather than heard:

/knock knock knock/ (silent pulse) - - / (silent pulse) - - / knock knock knock

Figure 1 First two bars of Tchaikovsky’s 5th Symphony

Figure 2 Opening of “Joy Spring” (Clifford Brown)

Rhythmic Phrases in Speech, Music, and Movement

Rhythm organizes rhythmic feet (up to seven) into “rhythmic phrases,” also referred to as “breath groups,” as their duration is similar to that of the breathing cycle. Between the phrases there is some kind of break—a short pause, a drawing out of the final sound or movement, or a change of tempo or other discontinuity. In music, where the beat usually has to continue uninterrupted, one or two silent beats may substitute for the pause at the end of the phrase. Sometimes phrases start off with a short, incomplete, and accent-less foot, known as the “anacrusis” (or, in music, the “upbeat”), and one of the accents in the phrase, the “nuclear accent,” will be more salient than the others, carrying the most important information of the phrase.

Rhythmic phrases plays a key role in the meaningful structuring of time-based texts. They “frame” the moves in the ongoing communicative act, as demonstrated in this example, which is an extract from a research interview with a radio announcer (the phrases end with a double oblique stroke and are enclosed in square brackets, and the nuclear accents are capitalized):

[I've read/ news at all/ SORTS of/ places and the the//] [blokes that/ write the news/
HERE//] [EM//] [CERTainly//] [far/ EASier to/ read//] [and that's/ not just because
 I'm/ working here/ NOW//] [than/ Any news I've/ read anywhere/ else//]

Three things can be noticed. First of all, each rhythmic phrase propels the announcer's train of thought a step further (or buys him some time to do so, in the case of *em*). Second, the phrases do not correspond to syntactic units, something which becomes even more clear if the phrases are written as separate lines:

I've read news at all sorts of places and the the
 Blokes that write the news here
 Em
 Certainly
 Far easier to read
 And that's not just because I'm working here now
 Than any news I've read anywhere else

Finally, the whole of the extract forms a larger scale rhythmical unit, the “rhythmic move,” followed by a longer pause, and functioning as a stage in the unfolding of the generic structure of the interaction (in this case a “response turn” in the interview). Such moves tend to be up to seven or eight phrases long, and experimental phoneticians have found that it is at the junctures between phrases and moves that the information in the previous phrase or move is “processed” and stored into memory (Abrams & Bever, 1969; Wingfield, 1975).

Martinec's (2000) hierarchical approach to rhythm analysis includes even further levels, beyond the “foot,” the “phrase,” and the “move” (he speaks of “waves”—“first order waves,” “second order waves,” “third order waves,” and so on), and he convincingly demonstrates that there is isochrony at all these levels. In other words, the time interval between the nuclear accents of the rhythmic phrases in a move (e.g., between *sorts*, *here*, *em*, *certain*, *easier*, and *any* in the example above) is also perceptually equal, and the same applies to the time interval between the most salient accents in rhythmic moves.

Regularization

The rhythmic structure of the research interview extract above differs in three ways from that of verse or music. First, the number of syllables per rhythmic foot varies, from one (e.g., in *here*) to five (in *not just because I'm*). Second, the number of rhythmic feet per phrase also varies, from one (in *em*) to four (*I've read/news at all/sorts of/ places and the the*). And finally, the tempo varies: In the “parenthetical clause” (*and that's not just because I'm, working here now*) he speeds up, shortening the duration of the rhythmic feet (there is of course also variation within the rhythmic feet, because the rate of utterance of *not just because I'm* has to speed up to make it isochronous with *working here*).

When the same speaker reads the news, his speech becomes more regular. Now almost all his rhythmic feet have three syllables, except for the phrase-final ones. The number of rhythmic feet per phrase also becomes more regular, and the tempo more even.

[the con/tainership/Asian RE/NOWN//] [is/due to leave/BRISbane to/day//] [with a con/signment of u/ranium/ YELlowcake//]

In metric poetry, regularization goes even further, and the traditional names for different kinds of meter and line structure are based on this. Rhythmic feet of two syllables are either “iamb” (short–long) or “trochee” (long–short), and rhythmic feet of three syllables are either “anapaests” (short–short–long) or dactyls (long–short–short). Lines may have two rhythmic feet (“dimeter”), three rhythmic feet (“trimeter”), four (“tetrameter”), five (“pentameter”), or six (“hexameter”), and so on. The following line from a Gershwin song, for instance, is a dactylic pentameter:

It's/ very/ clear our/ love is/ here to/ stay

The interpretation of meter goes back to Aristotle's fourth-century BC *Rhetoric and Poetics* (1954). According to Aristotle some meters were “high” and “noble,” others “common” and “ignoble.” The dactylic hexameter was the “heroic metre,” the “gravest and weightiest of metres,” while the iambic and the trochaic were “metres of movement” suitable for dance (“the trochee is too much akin to wild dancing: we can see this in tetrameter verse, which is one of the trochaic rhythms,” he wrote in the *Rhetoric* [1954, p. 181]). Today's poetic rhythms may be iconic, as Fonagy has shown in his analysis of a poem about a hunting expedition (1976, p. 15): “The rhythmical structure conjures up the picture of a merry chase. The anacrusis, the levelness of the tone, the repression of stress, and the relatively fast tempo symbolize the first part of the chase.” But they may also carry interactive meaning, stemming, for instance, from the basic function of accents to make some syllables more important than others. In didactic speech, but also, for instance, in highly excited speech, every syllable will be made important, and it is this which, in the given context, makes the speech “didactic” or “excited”:

[/that/is/sim/ply/fan/TAS/tic//]

Musical rhythm is typically regularized in three ways, first by the time signature, which stipulates, for instance, two, three, or four “beats” per rhythmic foot (“bar”), with the first (or, in the case of 4/4 time, the first and the third) beat accented (unless there is syncope). But just as speakers may squash many syllables into a single rhythmic foot, so composers and performers may squash many notes into a single bar, often in stylized ways, for instance by replacing single notes with “dotted” eighths, in a long–short rhythm (DAA de DAA de DAA). Second, the number of rhythmic bars per phrase tends to be

regularized, usually to four per phrase, or some multiple of it. And third, the tempo tends to remain constant throughout the whole of a song, or sonata movement, or other piece, so that the pauses between rhythmic phrases have to be replaced by “rests,” silent beats.

Rhythmic Integration of Different Time-Based Modes in Film

Films and television programs integrate different rhythms—the rhythms reproduced on film or video (those of the actors’ movements, those of the dialogue or narration, and those of the music or other sounds or both), and the rhythms stemming from the process of filming itself (the rhythms of camera movements and edits). In a given scene, one of these, usually either the action, the speech, or the music, provides the basic “beat” of the scene. The others are then synchronized to this rhythm during the editing and sound track laying process. In a dialogue scene, for instance, there is synchrony, not just between the actors’ movements and the dialogue, but also between these and the edits, which will coincide exactly with accented syllables (or sometimes unaccented syllables, in a kind of syncopation). In action sequences, the cuts will coincide with the accents of actors’ movements. In a typical scene, an actor may enter a room, step toward a table in medium tempo, and look at a letter that is left there. That is the first “phrase”:

[Step step/ step step/ step step/ STOP AND LOOK//]

Then he may slowly lift the letter and bend his head to read (a second phrase), after which the audience will get a glance at the letter, during two “silent beats”:

[lift letter/ bend head to look/ (silent beat) - - / (silent beat) - -//]

Finally, in a suddenly accelerated tempo, the actor may throw the letter on the table and hurry out of the room, slamming the door behind him:

[Throws letter down/ step step/ step step/ step step/ SLAM door/ (silent beat) //]

The editing will take its cues from the rhythmic structure of the acting. There may, for instance, be a cut to a close shot exactly as the actor stops, in the first phrase. There may then be a cut to a close-up of the letter exactly on the first silent beat, and again, a cut to a medium shot of the actor exactly as he throws the letter on the table. Finally there will be a dissolve at the end of the scene, over the silent beat. But editing may also be cued by music. The extract in Figure 3, from an anonymous travel film called *Latin American Rhapsody*, shows Van Leeuwen’s method of rhythm transcription (cf, Van Leeuwen, 1985, 2005). The scene is marked off from the preceding and following “moves” by a break in the music and a drum roll, and contains three rhythmic phrases, played on a flute. There are four shots, each beginning on the first accent of a rhythmic phrase, except for the last one, which begins on a silent beat that comes where a fourth phrase might have been expected, but does not eventuate, because the end of the third phrase has to be lengthened to signal the end of the scene. Note that the onset of the actors’ movements is synchronized to the musical accents through the editing process. The transition to the next move is signaled by a change in loudness and a change in tempo and instrumentation.

Figure 4 shows Martinec’s approach to multimodal rhythm transcription in the analysis of a 19-second segment from Sergio Leone’s *Once Upon a Time in the West*. In the excerpt, Jason Robards washes his face in a basin and answers Claudia Cardinale’s question about what Charles Bronson is doing outside. The different waves (rhythmic feet, phrases and

Figure 3 Rhythmic analysis of a scene cut to music (Van Leeuwen, 2005, p. 188, © Routledge)

moves) in each mode (action, speech and music) have their own rhythms, with peaks at the relevant accents. While speech and action are synchronized, the music has its own timing, and the zoom in on Robards's face does not begins until after he has turned his head. In contrast to the extract in Figure 3, which, in Martinec's terms, was "monochronic," this segment is "polychronic."

Rhythmic Integration in Everyday Interaction

In the 1960s and 1970s a number of American researchers began to engage in the highly detailed analysis of rhythm in everyday interaction. The medium of 16 mm film, recorded at high speed (94 frames per second), made it easy to slow down, speed up, and stop-frame body movement, and was therefore ideal for bringing out the subtleties of interactive rhythm and the rhythmic integration of behavior in interaction. Films were made, for instance, of people engaged in conversation (William Condon reportedly spent a year and a half studying four and a half seconds from Gregory Bateson's film of a family eating dinner); classrooms ("a class that is going well develops its own rhythm"; Hall, 1983, p. 166); and children in a playground, where the rhythms of children playing in different parts of the playground were in sync, not only with each other, but also with those of a girl whose "skipping and dancing and twirling" from group to group appeared to "orchestrate the movements of the entire playground" (Hall, 1983, p. 169). The conclusion was that "individuals are dominated in their behaviour by complex hierarchies of interlocking rhythm, comparable to fundamental themes in a symphonic score (Hall, 1983, p. 153), "locked together in a dance which functions almost totally outside awareness" (p. 154), and that rhythm provides the basic building blocks of behavior. Erickson (1982) similarly studied rhythmic integration in a dinner conversation, using musical notation with a staff for each participant, and concluding that "rhythm seems to be the fundamental glue by which cohesive discourse is maintained in conversation" (p. 65).

Wave Graph D. *Once upon a Time in the West*

Figure 4 Rhythmic analysis of a scene from *Once Upon a Time in the West* (Martinec, 2000, p. 297) © 2000 the International Society for the Arts, Sciences and Technology (ISAST)

Although there has been some take up of nonverbal communication (and hence multimodality) in conversation analysis (e.g., Ochs, 1979; Erickson, 1982; Goodwin, 2001), the study of rhythm has not been given the attention it deserves, and the pioneering work of scholars like Hall, Condon (e.g., 1978) and others (e.g., Erickson, 1982; Scollon, 1982) has only rarely been followed up. This is regrettable. Rhythm clearly plays a fundamental role in the phenomena that have preoccupied conversation analysts, such as turn taking, repairing disturbances in the flow of communication, and so on. Perhaps the reason is that rhythmic analysis is complex and requires a great deal of patience. It is nevertheless to be hoped that the study of rhythm will, in future multimodality research, regain the central place it so clearly deserves.

Multimodality and Ritual

GUDRUN FROMMHERZ

The systematic use of multimodal methodology to investigate human ritual behavior is relatively new. Informed by multimodal theory, methods and practice evolving from work by Scollon and Scollon (2003), Norris (2004), and Norris and Jones (2005), Frommherz (2009a, 2009b, 2010) presented a first account of multimodality in ritual by emphasizing the analysis of the mediated action (Wertsch, 1991) in ritual engagement over an often philosophically informed discourse of ritual in the historically difficult terrain of ritual studies. Specifically, Frommherz attended to ordinary real-time actions as they were performed during the ritual making of the Indian Aipan art, such as grinding rice, pouring water, dissolving ochre soil for producing the traditional dyes for the religious paintings, and to the intricate processes of commencing a new painting.

As an academic discipline, ritual studies has evolved from questions originally arising in the history of religion, philosophy, and evolution theory, as well as in cultural anthropology, sociology, and psychology. Bell (1997, p. xi) delivers a broad definition of ritual “as a complex sociocultural medium variously constructed of tradition, exigency, and self-expression” that integrates several, more exclusive, interpretations of ritual as either primarily archetypal conduct (Eliade, 1959), anthropological evolution (Tylor, 1958), communal order (Smith, 1969), sociological construction (Durkheim, 1915), psychological mode (Freud, 1946), or neurobiological imperative (d’Aquila & Laughlin Jr., 1996). Because of the cross-disciplinary character of ritual and the transient typologies of ritual forms that blur boundaries between ordinary and ritual actions, faithful disciplinary inquiry remains problematic. Notwithstanding varying and at times conflicting definitions of what exactly constitutes “ritual” or “ritual-like behavior,” ritual routinely arises at the nexus of ceremonial practices, sanctified objects, sacred meaning, and controlled temporal rhythms, with configurations of any one of these elements and their combinations varying greatly. While these and other elements contribute to what ritual may mean at any one instance of application, it was only since the late 19th century, notably through the work of the French sociologist Émile Durkheim (1858–1917), that a functionalist approach to ritual challenged existing notions of ritual as a deterministic, largely involuntary human condition. Durkheim (1915) emphasized the social functions of ritual and proposed ritual as constructed socio-communal behavior rather than as a psychological, and often universal, human quest.

The interest in the social purposes of ritual spawned new methodological requirements that were mostly answered with ethnographic fieldwork aimed at supplementing the predominantly theoretical-philosophical discourse in religious studies with real-world data. Much of the research into ritual still relies on a combination of scholarly discourse, involving theories in any one or several of the academic disciplines that inform ritual, with ethnographic inquiry that explores the social application of cultural resources in a given community of practice. As with other theory-informed research, the relationship between reflective analysis and data remains complex and ambiguous (e.g., Bell, 1997; Dusek, 2006). Aside from an essentially problematic relationship between disciplinary theory and research methodology, established ethnographic research into ritual behavior is often constrained by questions of researcher perspective and participant involvement, inconsistencies between

instruments of data collection and methods of data analysis, or the challenge to adapt static research tools to dynamic research questions.

Multimodal methodology as proposed by Kress and van Leeuwen (2001), Scollon and Scollon (2003), Norris (2004), Norris and Jones (2005), and Jewitt (2009) mitigates several such methodological constraints by offering a meticulously data-driven research approach optimized for the microanalysis of “discourse in action” (Norris & Jones, 2005, pp. 3–14). Multimodal methodology is a theoretically grounded and rigorous research method. Because of its interdisciplinary nature, multimodal methodology delivers a flexible approach to the study of changeable, momentary, and often ambiguous human endeavors such as ritual actions. In particular, multimodal interaction analysis (MIA) (Norris, 2004), which has for the most part outgrown the linguistic origin of multimodal discourse analysis, delivers an inclusive methodological framework with both tools for data collection and transcription, and methods for data analysis of the mediated action. As a tool for data collection, MIA encourages, for example, the use of digital audiovisual data—ideally in multi-camera settings—in preference to single-mode data collections such as written field notes, or audio records alone. While an audiovisual approach to data collection is not unique to multimodal research, multimodal analysis strongly emphasizes multimode transcription and multimode interpretation. Aided by digital technology, time-coded multimodal data can be slowed down, zoomed in on, and almost infinitely enlarged in order to reveal otherwise hidden temporal and spatial relationships in ritual actions (see Dicks, Soyinka, & Coffey, 2006, and Murphy, 2008, for case studies in digital ethnography).

The acknowledgment of dynamic relationships between various communicative modes such as speech, gesture, gaze, body position and movements that together construct complex communicative meaning holds a prime position in multimodal research. Most ritual forms rely on the concurrent use of a number of modes, often in ways untypical for non-ritual actions, for the construction, reenactment, and delivery of ritual meaning. Multimodal microanalysis not only recognizes the existence of modal variations across different uses of ritual, and between ritual and other forms of social interaction, but also, and more importantly, records how such modal shifts occur in real time. MIA’s process-oriented perspective on the mediated action, and its recognition of the practices of ritual performance, ritual construction, and ritual change, enables a focused investigation of real-time processes in ritual behavior. The microanalysis of the dynamic relationships of multiple communicative modes, and their real-time application in the actual sociocultural environment at a given moment, distinguishes multimodal inquiry from established ethnographic research.

Drawing on Norris’s (2004, 2009) concepts of modal configuration and modal density, Frommherz (2010) produced a first comparative study of modal transformations in ritual behavior using multimodal methodology. With her fieldwork on religious-folklorist Aipan art, Frommherz investigated the various ritual uses of decorative patterns by the Kumaoni people of the Indian Himalayas in order to celebrate religious and seasonal festivals and to honor their gods (see Shah, 2006, for an introduction to the art forms of Aipan). Frommherz (2010) presented evidence of a significant level of personalization in the way communicative modes were used during the ritualized processes of creating the art form. For example, Frommherz demonstrated that the artists, traditionally the women of the house, recurrently shifted modal attention away from the prescribed temporal flow of a ritual to personal, inner time. In such instances, the artists delayed or accelerated key moments in ritual performance in order to synchronize personal, spiritual needs with the flow of the concurrent ceremony. As a result, the original temporal rhythm of the ceremonial act was effectively altered. In other instances, modal attention was notably directed toward mundane proceedings in a ritual performance, for example the handling of tools and vessels, rather than, as would appear natural, on the sacred objective of the ritual.

Following her observations of modal transformations in ritual actions, Frommherz (2009b, 2010) proposes a dialogic relationship between dutiful ritual performance and creative ritual construction. This dialogic perspective departs from the view of ritual as imperative reenactment (Eliade, 1959) of largely invariable ritual forms and meaning (Rappaport, 1999), and indicates a dynamic interchange in which ritual form shapes personal experience while personal experience, conversely, constructs ritual form (see Bruner, 1986, for a discussion of the dynamic relationship between semiotic expression and personal experience). Frommherz (2010) argues that it is routinely the social actor who constructs his or her personal ritual experience in real time by deliberately and purposefully guiding modal attention and balancing modal configuration. The finding of personalized transformations in modal application indicates that, in addition to Durkheim's social constructive approach to ritual with a primarily communal, and therefore public, purpose, ritual concurrently engages a personal, private space for the individual performing the ritual. With such insights, ritual behavior arises as a means of personal identity construction (Frommherz, 2009a) far extending Durkheim's communal view of ritual.

Norris's (2004, 2009) hierarchical action model provided another conceptual key to Frommherz's investigation of modal transformations in ritual actions. The hierarchical action model proposes social actions to be comprised of numerous lower-level actions which themselves are made up of further lower-level actions, thus enabling an almost indefinitely fine graining of actions on a sliding scale of scrutiny. The significance of concomitant multi-level actions, however, is not limited to the tasks of analyzing social actions. Frommherz observes that the hierarchical action model also serves as an approach to conceptualizing ritual processes in the social actor. According to Frommherz (2010), the social actor during ritual performance regularly concentrates on the performance of lower-level actions such as repetitive, ordinary movements or gestures, and even on lowest-level actions such as deep, regular breathing, in order to create the spiritual momentum of a ritual action that distinguishes ritual actions from inattentive, habitual, everyday actions. These investigations led to the recognition that modal attention on micro and macro levels of ritual engagement are essentially asynchronous: while the macro focus remains on the sacred, modal micro focus attends to the profane (see Durkheim, 1915, and Eliade, 1959, for different discussions of the aspects of "sacred" and "profane"). More specifically, Frommherz (2010, p. 220) proposes that it is exactly by means of modal concentration on the "small, simple and mundane" that sacred meaning arises on a much higher level. While much of the earlier discourse on ritual assumed the ritual performer's attention to be fully dedicated to the sacra, that is the sacred core and purpose of the ritual (eventually leading to a trance-like state or what Durkheim, 1915, calls "collective effervescence"), the micro-analysis of ritual actions suggests the contrary: the performer's attention is essentially away from the larger meaning of the ritual and close to the profanity of mundane handling of ritual activities.

The significance of Norris's (2004) framework of multimodal interaction analysis on ritual behavior has not yet been fully explored. However, it can already be seen that MIA will continue to provide a robust methodology to scrutinize areas of ritual that were traditionally inaccessible; ritual resemiotization is such an area. This subject is largely untouched by premultimodal research. Resemiotization (Iedema, 2001, 2003) refers to the materialization of language resources or discourse into social practices, but also entails the transformation of semiotic meaning between different sociocultural contexts and communicative systems (what Bernstein, 1990, calls "recontextualization"). With her work on the temporal rhythms in ritual actions, Frommherz (2011) presents a principal analysis of temporal resemiotization between sacred and profane activities. Her findings indicate that the integrity of ritual meaning depends on temporal rhythms above other semiotic resources such as material cultural tools or mediational means (Wertsch, 1998). The discussion of

temporal density in ritual, a concept appropriated by Frommherz (2011) from Norris's (2004) idea of modal density, suggests a sliding scale between everyday and ritual actions. The degree of ritualization in actions is, according to Frommherz, determined by the type, level, and complexity of temporal synchronization in social actions. Temporal synchronization refers to a purposeful and deliberate alignment of the inherent duration of a ritual activity (e.g., taking a ritual bath) with its associated organizational time cycle (e.g., the circadian or 24-hour time cycle). Subject to their wider application in ritual research, the notions of temporal density and temporal synchronization in ritual engagement may deliver reliable tools to delineate ritual from ritual-like actions, and to distinguish these from everyday actions.

Multimodal methodology—with its close scrutiny of precisely how ritual actions are performed; how modal attention is shifted; how semiotic systems are appropriated; and how temporal rhythms are orchestrated—is opening new avenues for microanalysis of ritual, which likely will clarify and further define the purposes, functions, and meanings of human ritual behavior.

Multimodality and Software

THEO VAN LEEUWEN AND EMILIA DJONOV

In its broadest sense, the term “software” contrasts to “hardware” and applies to any computer features that cannot be physically manipulated. This includes features invisible to the average computer user such as algorithms, text files written by programmers in source code, and their translations into computer-executable, binary, code. In a narrower sense, software refers to programs that operate computer systems (systems software such as Windows, Linux, or Mac OS) and programs that allow users to achieve certain tasks (applications software), for example to write a letter (MS Word), send an e-mail (Eudora), edit an image (Adobe Photoshop), or compose a tune (ProTools). Though common in both everyday and professional contexts, such distinctions do not offer a way of understanding how and why “software structures and makes possible much of the contemporary world” (Fuller, 2008a, p. 1), the questions that motivate the recently established field of software studies, first proposed by Lev Manovich (2001).

Rejecting the widespread view of software as a neutral tool, software studies seeks to open computer science to critical perspectives from the arts, media, and cultural studies, and to highlight the creative opportunities which the “technicity” of software affords. So far contributions to the field have focused on a range of diverse aspects of computing—for example, weird or obfuscated programming languages, elements of graphical user interface design such as the button, system event sounds such as the Windows startup tone, and preferences palettes—as well as on their potential to reflect power relations, reveal aspects of the design process, and offer insights into the identities of computer users. (Many of these contributions are compiled in Fuller, 2008b.) However, these aspects tend to be discussed in isolation from each other and without reference to analyses of actual computer use, perhaps because software studies, so far, lacks a unifying social theory of meaning-making, one that can explain how different semiotic resources interact to create meaning in relation to the sociocultural contexts in which they are co-deployed.

Formal, cognitive, and social-functional aspects of software have all been explored in studies in computer semiotics (Andersen, 1997), human–computer interaction (de Souza, 2005), and the semiotics of programming (Tanaka-Ishii, 2010). These studies propose abstract classifications of different signs in computing and recognize that software incorporates verbal, visual, tactile, and aural resources but offer no model for analyzing their multimodal interaction in software design or use.

In principle, applied linguistics has the capacity to develop a stronger understanding of software as a powerful technology for making meaning. Given recent advances in the study of multimodality, it is well placed to investigate how software enables and constrains communication; how it recontextualizes preexisting, nondigital, meaning-making practices; and how it enriches or restricts our understanding of the semiotic potential of different resources (verbal, visual, audio, and kinetic) and their coarticulation. To date, however, applied linguists have studied software predominantly indirectly—as a tool for learning or a tool for linguistic analysis, rather than as an object of analysis itself—and rarely from a multimodal semiotic perspective.

In the field of language teaching and learning, software has been studied as a tool for language learning (see Chapelle, 2003), and for analyzing and evaluating the language use

2 MULTIMODALITY AND SOFTWARE

of learners (see Marsden, Myles, Rule, & Mitchell, 2003). Applied linguistics research has also informed the actual development of software for language learning and the design and choice of materials and activities for computer-assisted language learning. Scholars have analyzed learning materials from a multimodal perspective (see, e.g., Kaltenbacher (2004) on language-teaching CD-ROMs and Knox (2008) on TESOL and online news genres), though usually without considering the software employed in either their design (e.g., Web design software like Dreamweaver) or use (e.g., Web browsers such as Mozilla Firefox and plug-in applications such as Flash).

Applied linguists also use software as an analytical tool in corpus linguistics, where the affordances and limitations of various applications for building and annotating corpora and comparing frequency patterns of words and collocations across large numbers of texts are of fundamental importance (see McEnery, Tono, & Xiao, 2006). Here, too, software is viewed as a tool for, rather than an object of, analysis. Recent research has also proposed models for building, annotating, and transcribing multimodal corpora, including software to support these models (Baldry, 2004; O'Halloran, Tan, Smith, & Podlasov, in press). Such models have the potential to increase the empirical basis of multimodal discourse analysis by strengthening the replicability of multimodal analyses and allowing large numbers of multimodal texts to be compared in order to identify the similarities and differences between various genres (Baldry & Thibault, 2006; Bateman, 2008). Software is also the most powerful means for visualizing patterns in the use and aggregation of primitive features such as color and lines in large datasets, and for tracing changes in these patterns over time (Manovich, 2007). Yet, multimodal corpus analysis faces many challenges. As few nonverbal resources can be automatically coded (see Carter & Adolphs, 2008), labor-intensive manual annotation remains necessary. Verbal labels are incompatible with the nondiscrete nature of nonverbal choices which vary by degree (topologically) rather than type (typologically). Coding may also background the fact that, like words, nonverbal units may simultaneously fulfill different functions (convey an idea, construe an interpersonal position, and contribute to cohesion), and participate, in full or in part, in various larger units. Finally, even software-supported multimodal transcription has difficulty showing the spatiotemporal unfolding of meaning and the interaction of different semiotic choices in dynamic media such as film (O'Halloran, 2004).

A different perspective characterizes Jewitt's (2004, 2006) research on the relationship between technology, literacy, and learning. Her analysis of the use of computer games in the science classroom reveals four main aspects of the relationship between software design and use:

1. Applications differ in the degree of design and customization freedom they afford. A software may allow its users to apply only pre-given resources (e.g., game rules), or to modify resources, or import or design new resources, and these modifications and additions may or may not become part of the application.
2. Applications vary in the degree and type of specialized knowledge and associated genres built into them. In one of the applications studied by Jewitt (2004), for instance, programming an object to move required composing an equation consisting of lexical instructions and mathematical symbols; in another it only required pressing a button. Such variation is not restricted to the applications studied by Jewitt. Paint, an application within Windows, for example, is more accessible to the average user than Photoshop, which has many more (and more sophisticated) options for creating and editing image files, and presupposes a higher awareness of visual art and graphic design practices and principles.
3. A software may support different uses, with more or less clear boundaries between them. In one of the game-building applications studied by Jewitt, students had to

alternate between programming and playing, while in another they could modify the rules of the game while playing it.

4. A software's user interface plays a key role in determining how an application is used, enabling some and constraining other possibilities for meaning-making and learning.

Yet, to understand how software enables some and constrains other possibilities, semiotic studies of software need to look both behind and beyond the user interface. This is not to deny the value of analyzing software as a meaningful spatiotemporal arrangement of various units. Such analysis, for example, can help identify whether a software's design favors certain options over others by making them easier to find and use. Applying preset paragraph styles in Word takes less time and effort than creating new ones, for instance. Also, software may be biased toward certain modes and media (e.g., Word offers rather limited options for manipulating images compared to Photoshop) and toward certain configurations of modes and media (e.g., built-in design themes in PowerPoint have associated font and color schemes as well as graphical elements such as frame decorations or bullets), and interfaces may "recommend" or impose particular sequences of steps within applications. PowerPoint 4.0, for instance, opens by asking users to select whether they want to open an existing presentation or create a new one. If a new one is chosen, they must then select one of four options: AutoContent Wizard, Pick a Look Wizard, Template, or Blank Presentation. The labels of options, too, may expose tacit norms. Custom animation effects in PowerPoint, for example, are categorized into "basic," "subtle," "moderate," and "exciting."

Existing understanding of how user interfaces privilege certain options for making meaning, and the effects this has on software use, can be further advanced by considering what lies behind the interface and modeling software as system (paradigmatically), in addition to analyzing it as text (syntagm). This entails cataloguing and classifying all meaning-making choices available within a software—choices of expression resources such as color, line, typography, and animation effects; choices of semantic relations (e.g., different degrees of generality, which may be signaled through indentation); and affordances for creating different genres (e.g., equation, cartoon, music video). Such modeling would allow a software's uses to be analyzed as instances of the software as a system, just as a business letter instantiates only some of the meaning-making potential of the language in which it is written. A software system can also be viewed as a reservoir of meanings from which its users develop their individual repertoires for different contexts of use. (On instantiation and individuation in social semiotics, see Martin, 2010.) While PowerPoint offers sound effects, for example, these are unlikely to feature in an inaugural professorial presentation. In addition, modeling a software as a system may reveal that it offers more choice for some semiotic resources than others (e.g., sound compared to typography in music software such as ProTools), and such discrepancies may be linked to the purpose(s) an application is designed to serve and the semiotic practice(s) it recontextualizes. Photoshop, for example, offers extensive choices for creating and manipulating images, and for recontextualizing visual arts, photography, and graphic design practices.

Finally, to understand the interaction between software design and use, multimodal software studies should look beyond software and consider how the meaning-making resources available within a software relate to those available in the culture in general. This would allow analysts to demonstrate how software may expand as well as contract the meaning potential of a semiotic resource such as texture or movement by presenting more or fewer options for manipulating this resource. It would prevent the risk of attributing changes in the semiotic landscape solely to software technology. Van Leeuwen (2008) thus argues that the use of PowerPoint and Excel in bureaucratic settings promotes a new form of writing, where language presents entities packaged as nominal groups,

leaving visual resources to connect these entities; and Yates and Orlikowski (2007), in an ethnographic study of the use of PowerPoint in corporate settings, define PowerPoint-supported presentations as a development of the business-presentation genre.

Clearly an applied linguistics approach to software studies has an important perspective to offer to contemporary language studies. It can reveal the “grammars” or resources for making meaning that are designed into software; investigate their uses, and the discourses and practices that regulate them; and consider the semiotic changes that result from the introduction of these important and powerful new resources in a wide range of settings.

Multimodality and Systemic Functional Analysis

JOHN S. KNOX

Introduction

Multimodality is the study of how multiple communication modes combine to make meaning (e.g., language, gesture, and proxemics; language, image, and layout). But multimodality is not a discipline or a theory; it is “a field of application” (Jewitt, 2009, p. 2) which transcends and draws on different disciplines and theories. The recognition that all communication is multimodal has profound implications for applied linguistics, and questions long-standing assumptions about the nature of language, and how it should be learned, taught, researched, and theorized.

Systemic functional multimodal discourse analysis (SF-MDA) draws on the principles of systemic functional (SF) theory, and it is this which distinguishes SF-MDA from other approaches to multimodality.

What Is SF Theory?

SF theory has a number of defining characteristics which are derived from systemic functional linguistics (SFL). SFL is a theory of language as a resource for making meaning in social contexts. The theory is generated through the study of written and spoken texts, and the contexts in which these texts make meaning. SFL is a functional theory; that is, its focus is not on the forms of language per se (though these, too, are important), but on the function of linguistic forms in context. SFL is also a systemic theory; that is, it accounts for meaning by positing meaningful systems of choices available for language users. To illustrate, if we study English texts, two of the choices that can be identified in clauses are declarative clauses and polar interrogative clauses. Such clauses differ in their structure. Consider:

Clause A: You must complete the form.

Clause B: Must I complete the form?

Clause A is a declarative clause, in which the subject (*you*) precedes the finite (*must*). Clause B is a polar interrogative clause, in which the finite (*must*) precedes the subject (*I*). There is a functional difference between the structure of these two clauses, and in SF theory, this difference in structure realizes a systemic opposition: a declarative clause as opposed to a polar interrogative clause, as illustrated in Figure 1.

This relationship between system and structure (called the system–structure axis) is the basis of SF theory, and is applied to different levels of meaning (e.g., phonology, grammar, and discourse semantics in SFL). It forms the basis of explanations and hypotheses about the relations between the levels, about the relations between text and context, and about other “dimensions” of analysis in the theory (see Martin, 2010).

Figure 1 Simplified system

One key aspect of SF theory, which has been widely applied in studies of multimodality, is the observation that there are three broad kinds of meaning (called metafunctions) in language. These three kinds of meaning (which are derived theoretically from systemic oppositions) are labeled in Kress and van Leeuwen's (1990, 1996) seminal "grammar of visual design" as

- representational meanings—construing our experience of the world (which maps onto the ideational metafunction in SFL);
- interactional meanings—construing relationships between the producer and receiver of a text, and the text (which maps onto the interpersonal metafunction in SFL); and
- compositional meanings—construing coherence between the elements in a text and the context (which maps onto the textual metafunction in SFL).

The terminology used to label the metafunctions in SF-MDA varies across studies and approaches (cf. O'Toole, 1994; Lemke, 2002), but the theoretical debt to the metafunctions of SFL is clear in each approach.

Another key element of SF theory which is important in SF-MDA is the identification of genres: consistent patterns of structure in groups of texts sharing similar social purposes (see Bateman, 2008).

SF-MDA

SFL focuses on meaning in context, and has long understood language as one semiotic resource among many (e.g., Halliday, 1978). Thus, SF theory has always been amenable to the study of semiotic systems other than language, and of the interaction between such systems in texts (i.e., SF-MDA).

An important early step in the progression of SF theory from language to other semiotic systems is Kress and van Leeuwen's (1990) *Reading Images*, motivated in part by "the need for a better understanding of all the things that go *with* the verbal: facial expressions, gestures, images, music and so on" (Kress & van Leeuwen, 1990, p. 1). This work was soon followed by the introduction of the journal *Social Semiotics* (in 1991), O'Toole's (1994) study of displayed art and architecture, and the extended version of Kress & van Leeuwen's earlier work (Kress & van Leeuwen, 1996). These last two works (by O'Toole and by Kress & van Leeuwen), in particular, have informed much of the subsequent work in SF-MDA.

SF-MDA began with the application of SF theory to the description of semiotic systems other than language. Kress and van Leeuwen's (1996) "visual grammar" illustrates this, with explicit systems, and the structures realizing them, developed and described for visual communication.

Other semiotic systems, such as music (e.g., van Leeuwen, 1999) and three-dimensional space (e.g., O'Toole, 1994; Stenglin, 2009), have also been described, as discussed below. SF-MDA has been concerned also with how different semiotic systems are integrated in

acts of meaning: One notable example of this is O'Halloran's (e.g., 2005) description of mathematical discourse as a combination of language, image, and mathematical symbolism. These descriptions of semiotic systems and investigations of multimodality "in action" vary in the extent to which they draw on the system-structure axis developed in SFL, or on other aspects of SF theory which have derived from the system-structure axis, or on both. The descriptions also vary in the extent to which they problematize the "theoretical borrowing" from one semiotic system (i.e., language) to others.

As a relatively young area of investigation, SF-MDA continues to explore a range of fundamental questions. These include, but are not limited to, whether (the same) three metafunctions operate across semiotic systems (e.g., van Leeuwen, 1999; MacDonald's discussion of music in Martinec, 2005); the nature of relations between semiotic systems (in particular image and language) in texts (e.g., Royce, 1998; Matthiessen, 2006; Bateman, 2008; Martin, 2010); and whether "levels" of meaning proposed for different semiotic systems have the same theoretical basis (e.g., Martinec, 2005; Baldry & Thibault, 2006; Matthiessen, 2006; Zhao, 2010).

In the subsections that follow, work that explores these and other questions is grouped according to the kinds of texts explored: two-dimensional, three-dimensional, and studies which explore the fourth dimension of time.

SF-MDA in Two Dimensions: Page and Computer Screen

Multimodal SF studies of (primarily) static, two-dimensional texts have looked at a wide range of text types produced in print and hypertext, including instructional materials and textbooks, illustrated books and picture books, print advertisements, and newspapers. The majority of this work has focused on educational and mass media texts.

Print instructional materials for the general public have been examined from an SF perspective. Software manuals in English and Japanese are analyzed by Martinec (2003), who found the Japanese manuals more explicit in their staging and their visual coding of instructions. English-language instructions for setting up a computer are analyzed by Stenglin and Iedema (2001), who found image, language, and their relations crucial to understanding the text.

In textbooks and teaching materials, the visual design of information has been shown to have an important role in the construction and reproduction of knowledge (e.g., Bateman, 2008). A study of the use of visuals in print, CD-ROM, and Web materials in three science disciplines in English (Jones, 2007) found differences according to discipline and medium, but overall observed "a relatively strong trend of covariation" (p. 117). Studies have examined the use of diagrams in discipline areas such as mathematics (O'Halloran, 2005), history (Derewianka & Coffin's chapter in Unsworth, 2008a), biology (Guo's chapter in O'Halloran, 2004), and economics (Royce, 2006). Chen's (2010) study of interpersonal meanings in English-language teaching materials in China found that the communication of the expected attitudinal stance toward the materials and classroom activities shifts from image to language over the progression from primary to secondary school, as "a personal way of expressing individual emotions gradually shifts to a more institutionalized way of evaluating people's behaviours and abstract concepts" (p. 72).

Text-image relations in children's picture books have attracted attention from SF-MDA researchers (see Martin's and Painter's chapters in Unsworth, 2008b; Tian's chapter in Bednarek & Martin, 2010), as has the growing use of CD-ROM and online materials in educational contexts (e.g., Unsworth, 2001; Jewitt, 2006; Djonov in Unsworth, 2008a; Zhao, 2008).

The visual design of newspaper stories has also been studied by Caple (see Bednarek & Martin, 2010), who describes the genre of the "image-nuclear" news story, which

uses a large photograph, a playful heading, and a caption to tell news stories and build the community of readers of the newspaper. Similar kinds of “play” between images and headlines can be found in the Greek and English news features analyzed by Economou (e.g., 2008). Economou draws on SFL to describe the different “evaluative keys” of photographs—from “objective” and “factual” images which “record” events, to more overtly “authored” images which provide more obviously subjective evaluation. Knox (2009) studies thumbnail images in online newspapers, and problematizes the boundary between image and language as separate systems.

The multimodal design of newspaper pages has also been studied from an SF perspective. Kress and van Leeuwen (1996, 1998) employ their visual grammar to describe print home pages, employing the compositional metafunction of their “visual grammar” to account for the top–bottom (ideal–real), left–right (given–new), and centre–periphery (centre–margin) organization of information on the page; Knox, Patpong, and Piriyaasilpa (see Bednarek & Martin, 2010) found a different pattern of visual design on Thai print newspaper front pages. Other aspects of Kress and van Leeuwen’s (1996) visual grammar are employed by Knox (2007) to describe the home pages of online newspapers, which present news in short “bites” of information as a result of historical developments in news reporting, institutional factors, and the constraints and affordances of the Web medium. An alternative account of the design of online newspaper home pages by Bateman (2008) argues that online newspaper pages have less in common with print newspapers than they do with other Web pages which list information.

SF-MDA in Three Dimensions: Space and Embodied Meaning

The best-known early work on developing a “grammar of space” is that of O’Toole (1994), who poses four ranks for analyzing architecture (building, floor, room, element). O’Toole’s approach to analyzing multimodality maps levels (or *ranks* in SF terms) horizontally, against the three metafunctions vertically. The resulting grid is then populated with functions and systems at each point. This approach to SF-MDA has been applied across a range of semiotic systems and multimodal contexts by O’Halloran, 2004; cf. Zhao, 2010), and specifically to three-dimensional space in museums.

Ravelli’s (2006) study of museum texts builds on an analysis of language in museums to describe exhibitions and the institutions that house them. Her conceptualization of the ranks of institution, exhibition/gallery, and exhibit/display is shared theoretically by Pang, who identifies the ranks of museum, gallery, area, surface/item (see O’Halloran, 2004). Stenglin (e.g., 2009) also theorizes the construction of space in museums, and three-dimensional space more broadly, metafunctionally, but does not employ O’Toole’s framework. Ideational meanings are construed in orbital (spaces designed around a central element) or serial (spaces designed to be experienced one after another, relatively independently) designs. Interpersonal meanings are construed by binding (the degree of “openness” in a space, which may leave a user feeling too exposed, comfortable, or too confined), and bonding (the construction of museum visitors’ attitudes toward exhibition content). Textually, the concern is with the prominence of different aspects of museums, as well as the possible paths through the museum and exhibition.

In addition to theorizing the meaningful organization of space, scholars working in an SF-MDA framework have described the use of space in human interaction, as language and gesture interact with the material environment in which they occur. Zappavigna, Clérigh, Dwyer, and Martin (see Bednarek & Martin, 2010), describe a youth justice conference where young offenders are brought together with a range of people from the community. In the conference described in these authors’ paper, one of the participants changes the seating pattern mid-conference so that the young offender can look at his

mother. It is not only the arrangement of the room (in this case) but how it is made use of that is meaningful. Teachers' use of visuals (including displayed verbal texts) and furniture layout is described and analyzed by Kress et al. (2005), who illustrate how English classrooms can be "read" (and "written") as multimodal signs which reflect the teachers' philosophies of teaching and learning, and their institutional practices (see also Jones's chapter in Unsworth, 2008a).

A relatively small number of SF-MDA studies have explored the relationship between gesture and language. The co-patterning in conference presentations of gesture with interpersonal meanings in language is described by Hood and Forey (2005). They found that, despite high levels of variation in gestures between individual speakers, gesture is an important resource for establishing alignment between speaker and audience. Similarly, Jewitt (2006) describes the role of gesture and embodied meanings in expressing the interpersonal relations between teacher and students, and also their attitude toward the reading of a poem. More detailed and systematic consistencies between experiential meanings in language and the gestures that co-occur with speech are identified by Martinec (2004). In the study by Zappavigna et al. mentioned above, gestures are mapped onto the phonological unit of tone group, and the study finds that gesture works with various semantic systems as the text unfolds (see Bednarek & Martin, 2010). Most SF studies of gesture indicate that their work is exploratory, and that much research remains to be done in this area from an SF perspective.

SF-MDA and Time: Movement and Trajectories

Some multimodal texts, such as music, sound tracks, film, and television programs, are "time-based": The unfolding of the text and its speed are a property of the text, rather than of the reader's ability to process it.

Music has been studied from an SF perspective most notably by van Leeuwen (e.g., 1999). SF-informed studies have also examined film and television texts, or filmic texts. A key issue in the analysis of such texts is their transcription, and different analysts use different transcription models in order to illustrate different textual features: Van Leeuwen (2005) illustrates rhythm and links between the information provided in/with shots; Pun explores the use of sound and silence in films; Tseng describes coherence across semiotic resources and modes in filmic texts (see Unsworth, 2008a). Baldry and Thibault (2006) make the point that some analytical purposes require a *macro-transcription* "concerned with the interplay between the texts' phases," while others require a *micro-transcription* to enable "a detailed description of the semiotic resources used in the meaning making process" (p. 166).

In addition to time-based texts, some online texts have been studied from the perspective of readers' trajectories through them. Knox (2007) argues that, with the development of shorter texts on online newspaper home pages, the ideological goals of news institutions play out across multiple editions of a newspaper, as readers interact with the "newspaper-as-dialogue" over much longer timescales than a reading of a single news story, or a single edition of a newspaper. Djonov's (2005) study of children's Web sites documents different readers' paths through the same site, demonstrating that different paths through a Web site, and even different amounts of time spent on the same page, can change the meaning of the text experienced by the reader. Such differences are related to readers' purposes. Zhao incorporates the dimension of time into her modeling of readers' paths through "educational interactives" ("enclosed" Web sites which function as educational games), theorizing the *critical path* or *traversal* as the unit of analysis (see Bednarek & Martin, 2010). The notion of *resemiotization* is developed by Iedema (2003), who traces the process of one text being "resemiotized" into another as part of institutional processes,

with meetings eventually resemiotized into building plans, which are eventually resemiotized into a building. These studies illustrate some of the ways in which multimodality has challenged traditional notions of what constitutes a text, and how we approach text analysis.

Conclusion

SF-MDA is still in the early stages of its development, and questions such as the number and nature of levels in nonlinguistic semiotic systems, whether all semiotic systems share the metafunctions of language, and how to most effectively theorize interaction between semiotic systems are still to be definitively answered (Martinec, 2005). Yet SF-MDA offers a consistent theoretical basis for describing multimodal texts, studying semiotic systems, and understanding linguistic texts not as isolated entities, but as instances of a system of meaning that is always in interaction with other complementary, related systems.

Multimodality and Technology

KAY L. O'HALLORAN AND BRADLEY A. SMITH

There is a close historical association between multimodality and technology, in two senses. First, technologies have enabled a significant expansion of the range of media by which humans communicate, especially in terms of recording, replaying, and transmitting across time and space (that is, mediating) multimodal discourse. This has in turn greatly increased the human capacity for multimodal communication and thus sociocultural development: for example, the printing press contributed to the evolution of science (Eisenstein, 1979) as well as art, through the capacity for individual (rather than societal, institutional) expression (Lotman, 1991); and digital technology has led to a significant expansion of the repertoires of human cultural exchange (e.g., scientific, artistic, political, economic, and so forth), rapidly altering social organizations globally as a result (for example, in terms of the speed of global information exchange). In the second sense, technologies have enabled researchers to study much more closely and effectively multimodal texts, again in particular because of the capacity to record, replay, and analyze multimodal discourse, but also in terms of technical means for analysis (e.g., instrumental, computational) which extend the human sensory capacities for perception: see, for example, the software Praat (Boersma & Weenink, 2010) and ELAN (Wittenburg, Brugman, Russel, Klassmann, & Sloetjes, 2006).

Technology can be viewed as the application of scientific knowledge in the creation of tools: the physical embodiment of abstract scientific knowledge. The discipline of engineering, for example, is specifically concerned with the development of tools to solve particular problems, based on scientific, mathematical, and other forms of knowledge, including linguistic knowledge. However the term—derived from the Greek *technología* (τεχνολογία): *téchnē* (τέχνη) ‘craft’, ‘art’ and *-logía* (-λογία) ‘systematic study’—can refer variously to tools themselves, the study of tools, and the abstract scientific bodies of knowledge which are applied in the development and use of tools. Li-Hua (2009) gives a discussion, which begins with the observation that “the attempt to define technology seems quite challenging,” depending upon viewpoints from various positions; and this may reflect the importance and ubiquity of technology within contemporary societies.

Multimodality, for linguists and semioticians, refers to the integration of two or more semiotic resources (including language) in the communication of meaning. Semiotic resources (e.g., language, image, gesture, architecture, and music) are “system[s] of meanings that constitute the ‘reality’ of the culture” (Halliday 1978, p. 123). The objects of multimodal studies include the systems and structures of semiotic resources; the inter-semiotic processes through which semiotic choices integrate to create meaning in multimodal texts (e.g., documents, videos, websites, 3D objects, and daily interactions and events); the multimodal artifacts and events themselves which constitute instances of discourse; and the media through which semiosis takes place (e.g., stone, wood, fabric, paper, paint and ink, heliograph and photograph, phonograph cylinder, magnetic tape and microphone, and digital computer software and hardware). The term “multimodality,” however, has other specific uses: for example, for computer scientists and engineers multimodality refers to forms of input and output devices whereby humans interact with computers through sensory modalities (visual, aural, and somatic).

Within the human sciences, multimodality thus implicates both abstract and physical phenomena in its study: the semiotic (e.g., abstract systems and structures of semiotic resources and intersemiotic processes through which semiotic choices combine to create meaning, as well as the actual multimodal artifacts and events); and the physical media through which semiosis takes place. From this perspective, technologies are implicated in the study of multimodality both as semiotic (multimodal) artifacts in their own right and as media which impact on multimodal semiosis (as the means of multimodal communication). In technology, as in signs in general, we see both the material and the abstract drawn into a significant relation, because both semiosis and “technics” are dependent on a fundamental materiality (see Innis, 2009). These two interrelated aspects of technology—technology as multimodal semiotic phenomenon and technology as physical means of semiotic mediation—are now discussed, before the impact of technology on multimodal semiosis (i.e., media as “semiotic technology”) and on the study of multimodality is reviewed.

Since Descartes and the severing of science- and humanities-based knowledge, studies of the physical (material) and abstract (semiotic) planes have been separated, with technology and culture likewise being treated as separate domains of study and practice; the former as an application of science, the latter the preserve of the arts and humanities disciplines. This separation has led to a general perception of technology as physical rather than cultural (semiotic) artifact. Van Leeuwen (in press) discusses the cultural separation of the semiotic and the physical in the distinction between modes and media of communication: for example, between the composition of a musical work (as abstraction, semiotic mode) and its performance (as materiality, expressive medium). Yet, he observes, while the medium has typically and traditionally been seen as “a physical condition of communication that provides specific affordances and imposes specific restraints” (its function to provide a faithful reproduction of higher-level meanings), it is in fact “also intricately connected to the ways we use language and other modes of expression, and to the ways genres of discourse and technological media evolve alongside of, and in connection to, each other.”

The technologies that enable and mediate human cultural exchange (that is, multimodal communication) can thus be seen as the embodiment of cultural knowledge in general, as part and product of that culture (e.g., Foucault 1977). Technologies, that is, are semiotic, cultural resources, shaped by and shaping sociocultural practice: Our tools are part of the meanings we create as semiotic beings, part of our cultural repertoire, as much as the ideas and abstract systems and structures we create in language and other semiotic resources. Technology can thus be studied as (multimodal) semiotic phenomenon, as suggested by Innis (2009) and others within the semiotics tradition, including Andersen, Holmqvist, and Jensen (1993), who present early studies of computational technologies, including the semiotics of programming languages, interface design, and so forth, from the perspectives afforded by semiotics. Anthropologists and archaeologists have of course long studied implements and other cultural artifacts as multimodal bearers of meaning: that is, as semiotic artifacts. In fact, from the social semiotic perspective spoken (as much as written) language can be seen as a very early, perhaps definitive human “technology”: a tool for adaptive engagement with our changing (material, social, semiotic) environment, with the body (vocal tract, arms, hands, face, and so forth) as medium.

Lotman (1991) discusses the profound influences of technological development on and as a part of wider human culture, and the relations with society. Citing written language as an example of a profoundly influential technology, Lotman (1991, pp. 782–3) observes: “There is a repeated pattern to the immediate consequences of a technological change: having acquired new powerful means, society first attempts to use them for old ends, increasing its possibilities only quantitatively”: to take the example of writing, in expanding the capacities for large-scale building projects and “expanding the volume of social memory,” primarily through bureaucratic record-keeping. However, there was “another,

more profound consequence of the advent of writing technology, drastically changing the very matrix of culture" (p. 783): the expression of individual and personal creativity which resulted from the ability of individuals to record independently of established authorities and institutions. Lotman (1991, p. 784) goes on to point out that a "somewhat similar process followed the invention of printing and the whole scientific and technological shift of the Renaissance" (see also Eisenstein, 1979).

These observations also apply to more contemporary developments. The capacity to record sound and moving image has greatly increased the power to mediate, and thus record and replay, multimodal discourses of social life that were formerly transient and ephemeral. The televised Kennedy–Nixon election debates of 1960 showed the social power of such mediation, as did the UK elections of 2010. The advent of contemporary interactive digital technologies such as the Internet and mobile communication devices are having similarly profound consequences, particularly via the media storehouse that is the Internet and its capacity to record and disseminate human discourse across a wide range of multimodal forms. The consequences of such developments for science and human cultural development in general are still unfolding; but historical perspectives point to the possibility of fundamental changes as a result.

For example, the current generation is undoubtedly the most literate in history—in spite of prescriptive concerns by educators about the immense variation in written orthographies and discourse styles now developing worldwide through SMS and other e-chat media—in the specific sense that a vast proportion of the world's population now use writing, via mobile phone and Internet chat, on a daily and habitual basis, a large proportion of whom would formerly have written only little, and in general only while in the classroom (that is, within restricted social contexts). Literacy—the use of writing to communicate—is now no longer the privileged preserve of the well-educated, while writing is now used for a large variety of types of discourse (spontaneous, dialogic, informal, and so forth).

However, mediation through written and other forms of communication brings its own constraints as well as new affordances, and the social consequences of mediating (and recording) such interactions through the constraints of writing are yet to fully emerge. Halliday (1985) makes the point that the invention of writing appeared as a result of the demands of new social functions, those associated with the move from nomadic hunter-gatherer to settled agricultural social organization and associated needs for record-keeping. As a result, writing does not include intonation, crucial to the sort of interactions and negotiations characteristic of the spontaneous dialogues (Halliday, 1985) found in electronic chat. Traditional technologies such as writing are clearly changing as a result, as they become incorporated, remediated, and recontextualized within the new media, the most dramatic being the written language as used for spontaneous, real-time dialogic interaction (e.g., the use of emoticons, intersemiotic integration with image and sound, and so forth). The consequences for the written language, if not for culture as a whole, may prove as dramatic as the invention of the printing press did for Renaissance culture.

The idea that the development and use of semiotic technology is motivated by and motivates the evolution of culture (as adaptation to social needs) is basic to social semiotic theory. Van Leeuwen (in press) discusses the ways in which new technologies have expanded the semiotic potential of cultures in direct relation to more general social needs. Rejecting the notion of technological determinism, van Leeuwen cites the example of radio broadcasting, a phenomenon which came about not with the invention of radio itself—which Marconi had projected as having limited, mainly pragmatic purposes, as a medium for ship-to-shore communication and the like—but much later as a result of new social geographies and demands, in particular the development of new city "garden suburbs." Comparison of the dates of the invention and later widespread use of the Internet also neatly illustrates the symbiotic relations of technology and sociocultural development.

The ongoing development and utilization of recording media for everyday multimodal discourse in general (as in sound recording, film, mobile phone, and Internet technologies) may in fact be said to have their origins in the cultural need for the capacity to mediate more than just that which is found in textbooks and novels. Writing, as language, has been and continues to be very important for human social life; but mediating the full range of human communication types enables for multimodal discourse events the same transcendence of time and space as writing has done for a very restricted range of social discourses for thousands of years. Yet there is a sense in which the verisimilitude of state-of-the-art media (including the latest sensation, at the time of writing, 3D cinema) obscures the fact of these being “virtual” rather than actual. Just as writing is an impoverished record of speech and of everyday multimodal discourse, what we experience in cinemas, through sound recording, and on the Internet are but representations of events rather than the events themselves, while the intended interpersonal flourishes of e-mail and SMS dialogue may not communicate, as many are discovering, the same subtleties of expression as are common in face-to-face multimodal discourse, with often dire social consequences. Meanwhile, it is possible to imagine now a world where the instantaneous transmission of even mundane multimodal discursive interaction can be effected via a diversity of media and yet still remain “on the record” potentially, in effect, in perpetuity; such records may easily be taken out of their original discourse contexts, again with often negative social consequences. We are yet to fully realize the implications of the limitations and affordances of contemporary media, while the very rate of increase in sophistication and power renders us complacent in doing so: We remain “bedazzled” by our technologies.

The same close relations of general culture and technology can be found between the development of technology and its use within academia (for research and teaching). However, here the relationship has clearly been a strongly causative one, with technological development driving the development of studies of multimodal discourse. For example, until the invention of sound recording, the study of linguistics was in effect the study of written language, a constraint that meant that most grammars were orientated toward the language found in writing, not that of the wide range of spoken discourses found across the landscape of everyday human social life. The invention of early recording technologies first led to the study of speech within phonetics and phonology in the early 20th century; but it was the wide availability of tape-recording technology that ushered in the widespread study of naturally occurring spoken discourse in the 1960s, revolutionizing linguistic theory and description.

The availability of film and then video recording has likewise undoubtedly been a key factor in the rise in scholarly interest in multimodal forms of communication, particularly dynamic audiovisual forms of discourse. Multimodal annotation software (e.g., Rohlfsing et al., 2006) has provided similarly useful tools for accessing and annotating audiovisual text; and it is perhaps not surprising that with these technologies, a distinct field of multimodal studies has emerged and flourished in recent decades, dealing with an increasing range of media types, including hypermedia such as Web sites, with their complex array and integration of different semiotic resources, texts, and subtexts, as well as with a variety of discourse types, including the mundane and the spontaneous.

Such technologies, however, can never be autonomous agents in the study of semiosis but rather are tools in the hands of discourse analysts (whatever their disciplinary persuasion). As Halliday and Greaves (2008, p. 19) observe, “modern computer-based techniques of analysis and representation . . . provide a much richer and more elaborate treasury of information than was available a generation or even a decade ago . . . they do not replace the human investigator; they do make the human investigator’s work more complex—but also more thorough and more revealing.” Today, computational technologies, particularly interactive digital media but also automated techniques of analysis, continue to offer an

increasingly sophisticated set of tools for accessing, analyzing, sharing, and otherwise processing multimodal data. They are particularly appropriate and perhaps essential for the analysis of those data created by computational media, and for the emergent complexity and detail that result from their application. The challenge for applied multimodal studies is to adapt and utilize such resources for the work of multimodal analysis.

The gulf that exists between oral and literate cultures is just one example of the intimate and profound relations between technology and multimodal culture. A similar gulf has been created in the past two hundred years between the cultures of successive generations by the ever-increasing range and sophistication of media technologies. To say we move in a new world, the digital information age, is already a cliché. Our challenge appears to be the navigation through and adaptation to not so much an actual, material environment as the virtual semiotic, informational environment—an environment of our own making, incorporating the discourses of many millions of multiliterate social agents; and yet an evolved rather than designed environment. Understanding the relations of technological culture and multimodal culture in general is crucial. Such an understanding must ultimately depend upon knowledge of the relations of the material and the abstract planes, and of the links and discontinuities between the cultures of the present and the past as carried through innumerable recorded and unrecorded acts of multimodal communication.

Multimodality and the Senses

JENS LOENHOFF

The ordinary or commonplace conception of the “senses” treats them as physical capabilities associated with specific organs, that is, the sense organs. It is believed that one can grasp the world of things, events, and existence by means of them. Insofar as reality is a correlate of sense perception, the senses act as generators of the phenomenal world. To have seen something with one’s own eyes, heard it with one’s own ears, or touched it with one’s own hands is deemed the most comprehensive source of evidence. Research into sensory perception is focused strongly on the modality of the senses, that is, on their specific and distinctive qualities, and the associated differences in performance of sight, hearing, touch, taste, and smell. Sensory multimodality can only exist where there is modality. This applies to the connection between sensory perception and the attribution of meaning essential to all processes of communication. Thus there are cultural ideas and practices which are only made possible by means of specific sensory modes: for instance, music is only possible through the medium of sound and geometry only through the medium of sight.

The isolation of the senses from one another, which, at first sight, seems to be confirmed by the separation of the individual sensory organs, led to a distorted comprehension of a complex interaction. This distortion not only affected how exteroceptive perception, which is focused on the external world, was understood, but also neglected the importance of proprioceptive and kinesthetic perception, which provide information about the position and location of the body as well as the type and manner of its movement. Whereas the multimodal unity which exists in practical performance of actions is dissolved and separated into its individual parts, theories of perception are confronted by the hitherto irreconcilable problem of having to provide an explanation for their interaction. Despite the occasional accessory assumptions, amplifications, and attempts at differentiation, over the course of the history of philosophy and science the model of the five senses has more or less remained an unquestioned certainty in definitions of human sensation. As a “proto-idea,” however, it becomes problematic as soon as a description of the function of human perception in the process of communication, which was always multisensory, is necessitated. If not before, it now becomes apparent just how inadequate an individuating description of human perception, focused on specific organs, actually is (Loenhoff, 2001). The corresponding aporia only dissolves when sensory perception is no longer divorced from action, and this action is itself comprehended as a senso-motory performance. Here, the senses do not act as individual organs independent of one another, but rather continue to be oriented toward each other, in order to interact as part of an integrated human orientational behavior (Gibson, 1983).

All processes of communication are dependent on sensory perceptions. It is possible to perceive without participating in communication, but not to communicate verbally or nonverbally without specific sensory perceptions. For this reason there is an asymmetric foundational relationship between sensory perception and communication. Perception and movement are always unified in the form of a senso-motory cyclical process (Lewkowicz & Lickliter, 1994; Gehlen, 1997, pp. 131–326). Not only do they make possible the practical orientation of the organism within its environment, but they also control communicative behavior. The production of acoustic or visual instances of communication would not be

possible without a feedback loop of this kind in the form of self-perception. The comprehension and production of symbolic utterances and the generation of communicative resources by the individual consequently take place within the medium of this corporeal organization (Merleau-Ponty, 1945). The senses do not act passively or as mere receivers of information in the processes of co-orientation, interaction, coordination of action, or within the context of modern technologies of communication. Instead, perception consists of an active social practice, entirely dependent on its context and the intentions and motives behind the act of perception in question. For this reason participation in communication and the appropriate and proportionate employment of the senses must first of all be learnt. The ability to draw attention to something collectively, the ability to allow others to observe specific occurrences through the agency of one's own body and to make it available to the perception of potential communication partners is an important basis for this learning process. Whereas perceptions take place within a social or communicative context, perception is reciprocally observed. The participants become conscious that this perception is perceptible for other people. Face-to-face communication is very much dependent on the reflexivity of perception (Ruesch & Bateson, 1951; Goffman, 1971). Thus the employment of the senses is also always shaped by socially and culturally specific rules relating to the proportionality of the perceptual behavior (Classen, 1993; Howes, 2009). This sharing process concerns mutually shared expectations, for instance, where one's gaze may be fixed, which parts of one's own body or that of another person may be touched, how movements are performed, or which verbal utterances are considered appropriate or otherwise. Communicative performances are directly dependent on whether they are available to the senso-motory organization of the human being. This means that they have to be tailored to (a) the perceptual readiness of potential communication partners, (b) their perceptual capabilities and standpoint, and finally (c) the material perceptual conditions of the communicative situation.

(a) Even when perceptions often seem to happen to, impress, or even force themselves upon us, they are nonetheless a consequence of the willingness to pay attention to objects and events (Tomasello, 2008). The appellative inducement of the willingness to perceive, on the one hand, and the communication of this willingness on the part of a communication partner, on the other, form a unity within the process of communication, because they are reciprocally dependent on one another and can only be understood and explained from within the communicative context.

(b) Communicative messages of a verbal or nonverbal kind must always be tailored to the perceptual possibilities of the interactive partner. They have to take into consideration what can be seen, heard, or touched from the perspective and spatial position of the communication partner and his/her sensory capabilities. Verbal utterances only occur where one can be heard, and gestural motions can only take place where both participants share the same visual space and have sufficient room within which to make the gesture. Even simple, indicative gestures demonstrate the degree to which communicative partners reciprocally assume shared or mutual perceptions and, where necessary, produce, correct, or modify them by means of a shift in their own position in order facilitate communication.

(c) Processes of communication have to take into consideration the social situation, the associated rules of perception, and seek permission for perception to happen, but they also have to adapt to the material conditions of communication. These conditions are not random. On the one hand, these conditions have to do with the basic biological structure of the senso-motory systems and their orientation toward specific physical spectrums. On the other hand, they have to do with the situational conditions to which the communication has to adjust itself, such as background noise, diminished vision, a lack of freedom of movement, and so on. These material conditions present the perceptual faculties of the

communicating agents with particular challenges, which they must bear in mind in the production of their symbolic utterances, since these utterances are required to adapt their specific form to the material conditions of perception and the sensory capabilities.

All processes of communication are associated with a permanent evaluation of their perceptual conditions of enactment (Loenhoff, 2001). If these conditions change, the participants are obliged to seek other possibilities for mutual perception by use of their creative faculties in order that communication may continue. Perceptual processes thus have a significance which should not be underestimated for the monitoring of the success and efficacy of the communication. Alongside the above-mentioned factors, the perceptual conditions of enactment include knowledge acquired in the socialization process about dealing with that senso-motory bodily potential involved in the production and reception of communicative utterances. Without this knowledge about the use of one's own senses and the corresponding practical faculty, an important basis for strategic interactive behavior is lacking. This lack or absence is evident, for instance, when young children close their eyes and believe that in doing so they cannot be seen, because they themselves cannot see.

Focusing on exteroceptive perception, the isolated consideration of individual sensory modalities and attribution of perceptual performance to particular organs had a lasting impact and distorted our view of the interconnections of central importance to interactional analysis. Contrary to widespread preconceptions and naive theory, communication has always been a multisensory process. Symbolic expressions emerge from a communicative act or event in which gestures, facial expressions, as well as the verbal and nonverbal dimensions, co-constitute and interact with each other. From the perspective of the communicating agents, facial expressions, gesture, and language always form a unity in the production of meaningful utterances (Streeck, 1993; Kita, 2003). It is only when analyzed or viewed from the perspective of the external observer that they split into the elements occupying different levels and can be examined separately. Only the production of sound within the context of verbal communication demonstrates the interweaving or conjunction of varying feedback loops, because when speaking the movements in the area of the mouth are experienced by means of tactile and kinesthetic perceptions, while the auditory perceptual faculty oversees the production of sound. When this feedback is distorted, considerable problems involving articulation are the result (Howell, Powell, & Kahn, 1983). In the very same way, the movements of one's own body are experienced and controlled via kinesthetic and visual perceptions. Without these various feedback loops the production of indicative movements and other gestures would not be possible. All sensory processes involving proprioceptive perceptions, or which are associated with proprioception, facilitate this experiencing of oneself. All related occurrences of movement, experiencing of oneself, estimations of range, probabilities for success, as well as conditions for the realization of communicative processes by the senso-motory systems are only comprehensible from within the multisensory interconnection and uniformity of the bodily organization. In the process of communication, one's own acts of perception and movement are always focused on the communication partner via this inner feedback process, which is also constitutive for noncommunicative acts, and are additionally adapted to the partner's capability for perception and movement. Thus the recipient design of communicative utterances not only concerns the linguistic characteristics but also takes into consideration the perceptual perspective of one's communication partner, since this is of central importance for the purposes of comprehension.

Against this background, the notion that specific sensory perceptions can be ascribed to their respective communication channels is inappropriate to the reality of communicative process and leads to false heuristics. Due to its close ties to the transport model of communication, the model of sensory channels cannot properly address the function of

perceptual activities and sensory modes in the constitution and structuring of systems of communication. The entire metaphors of switching on and off as well as conduits, lines, and transport routes implies—and therein lies the ambiguity of the terminologically unsuccessful designation “channel”—a coincidence of reciprocal perceptual possibilities with the “opening” of entrances to communication in which appropriate conditions, not only for the constitution of informational processes, but for their success, can be seen.

The development of modern recording technologies and the attendant changes in analytical methods employed in empirical research on interactive processes have meant that greater attention is being paid to the multimodal nature of communicative processes (Van Leeuwen, 2005). The complexity of the coordination and co-production of verbal utterances can be recorded in a superior manner by means of new notational and transcriptional procedures. All forms of sensory perception and all semiotic resources available as a result of these perceptions can be included in descriptive and analytical works. Empirical investigations demonstrate how participants in communication exploit the possibilities for perception and motion available to them in order to start, continue, or end communication (Gullberg, 2003; Norris, 2004, 2009; Stievers & Sidnell, 2005; Goodwin, 2006). This empirical research demonstrates to what degree swapping speakers, so-called “turn taking,” is, in fact, a multimodal process characterized by a complex interconnection of verbal utterances, eye movements, indicative gestures, and other semiotic resources (Bolden, 2003; Mondada, 2007).

Recent research on modality and multimodality attempts to overcome the previous fixation on speech and writing as the single and most important means of communication (Kress & Van Leeuwen, 2001; Scollon & Wong Scollon, 2009). In the process, not only the particularities of singular modes of communication (speech, writing, image, music, gesture, glance, and so forth), but above all their interplay within communication have received attention. Numerous forms of communication are instantiated as a multimodal ensemble in which different semiotic resources are exploited simultaneously in order to achieve certain communicational aims (Kress, 2009). Semiotic resources are hence a correlate of sensory perception insofar as senso-motory systems, their specific efficacy and their cooperation, supply the enabling conditions for the constitution of modes of communication. A controlled hand movement, out of which the form of a gesture develops, must be proprioceptively received back by the producer of the gesture and simultaneously visually perceived by both communication partners. The same holds true for the glance, which, as a mode of communication, presupposes not only visual perception but also that the body is able to assume a certain position. Different communicative modes can emerge in the mediums of both auditory and visual perception, for the use of the senses enables the realization not only of a single but of several communicative modes. Interpersonal communication is above all characterized by the entanglement of multiple senso-motory functional circuits and the interaction of multiple communicative modes. The complex interplay of speech, eye glance behavior, gesture, facial expression, and the utilization of additional semiotic resources shows that communicative multimodality always presupposes multisensory processes of perception.

In multimodal communication, differences and performance variations in several senso-motory functional circuits are productively implemented in the coordination of actions. The analysis of the praxis of multimodal sensory perception demonstrates how the use of the body's senso-motory capacity can heighten the probability of coordination as well as initiate and direct the communication process. For this reason, interactive technologies of communication attempt to reproduce multimodality artificially in order to optimize the semiotic resources available to communication. This can only be done, however, within the framework of those possibilities which the senso-motory organization of human beings actually recognizes.

Multimodality and Time

GUDRUN FROMMHERZ

Temporality in language and in human interaction is a complex phenomenon. This, in part, results from a relative obscurity of time itself. As an observable phenomenon, time is relative to varying viewpoints that shift the very notion of time; physical, historic, economic, sociocultural, personal, and cosmic time each produce a different awareness of time. Further, some conceptions of time lie outside direct human experience and rather present intangible, abstract models: the instant, negative time, and space-time are such models. Notwithstanding the principal elusiveness of an inclusive epistemology of time, temporality is deeply embedded in human experience—in human beings collectively as a species, communally as social actors, and individually as subjective beings.

Traditionally, the scholarly disciplines of the humanities and of social sciences investigate temporality as a human capacity and often use time as an ordering scale of experienced events; most obviously so in the domain of history. However, it is possibly the field of philology that best summarizes human consciousness of time. Meyerhoff (1960) provides a comprehensive introduction to time both as a theme in literary arts and as an organizing narrative structure. The language philosopher Mikhail Mikhailovich Bakhtin (1895–1975) addresses the temporal dimension of the narrative act when he analyzes the *chronotope* or “time-space” in the novel (Bakhtin, 1981). The *chronotope* refers to the construction of time and space in and through texts, which would always already mediate the existing ideological meanings of a specific place at a certain historic point in time. With the *chronotope*, Bakhtin elevates the temporal-spatial dimension in texts to a unit of analysis in its own right. Bakhtin sees time and space as a single linguistic entity, highly interrelated and practically inseparable. Bakhtin’s idea of *chronotopicity*, first investigated in literature and then, increasingly, in a wider range of cultural artifacts, has influenced a large number of thinkers, critics, and researchers in the fields of literary studies (e.g., Howard, 1994; Brooker, 1995), linguistics and semiotics (e.g., Scollon, 1982, 2005; Scollon & Scollon, 2003; Schultz, 1990), social research (e.g., Fairclough, 1989, 1992; Wertsch, 1998), visual studies (e.g., Haynes, 1995), film studies (e.g., Stam, 1989; Sobchack, 1998), and feminism criticism (e.g., Hohne & Wussow, 1994), to name just a very few. It is possibly the clarity and precision with which Bakhtin outlined an inherently dynamic structure in mediated communication that left a lasting mark on the study of human interactions and the artifacts that arise from them.

Grown out of linguistics, multimodal methodology borrows from an integrated understanding of temporality that it applies to social actions at the core of its interests. Also here, a rooting in Bakhtinian thought is evident; Bakhtin understood the “event” (and all actions embedded within) as actualized instances of *polyphonic interactions* (Bakhtin, 1984) by social actors at the moment of active participation. An event, according to Bakhtin, is never monolithic, or single-voiced. Rather, the event is polyphonic with multiple voices (and other communicative modes) that create a communicative moment larger, or more complex, than the sum of its components. Also, the event could never be meaningfully described from the point of view of an objective, uninvolved, observer; events would necessarily be participatory and emerge at each instant of their temporal flow. Similarly, multimodal analysis does not so much recognize time as linearly progressing, and objective, events but as a multidimensional, and potentially subjective, phenomenon.

2 MULTIMODALITY AND TIME

In analyzing the temporality of events, Jay Lemke (2000, 2005, 2009) notes a *heterochrony* in human artifacts and in social actions. Heterochrony, a concept taken by Lemke from theoretical physics, refers to an exchange of information across distant scales in time, this way rendering linear, continuous time spontaneously discontinuous and nonlinear. Lemke demonstrates how actions instantaneously communicate across time, be it through material expressions (Lemke, 2000) or reflexive intentionality (Lemke, 2009). Ron Scollon (1939–2009) utilizes the ancient concept of time cycles to describe how humans habitually organize social actions (Scollon, 2005) along temporal scales (e.g., a day, a lunar cycle, or a season), a temporal entrainment that he calls *pacemakers*. These pacemakers identify social actions to be anchored in actuality, yet, at the same instant, embedded in a larger temporal dynamic. Building on Scollon (2005), Gudrun Frommherz (2010, 2011) observes a distinction between time cycles and *action cycles*—between the temporal organization of actions and the inherent timescale itself of an action. Analyzing relationships between the duration of a process and its intervals of occurrence, Frommherz (2011) notes instances of *temporal synchronization*, the purposeful alignment of social actions along their associated time cycles, and these with further action and time cycles. According to this proposition, a same action executed at different intervals along its respective time cycles would alter the *temporal density*, and with it the significance, purpose, and subjective experience of the action. Temporal density, a concept developed by Frommherz (2011) borrowing from Norris's (2009) notion of *modal density*, refers to a dynamic interplay between temporal complexity (i.e., quantitative temporal synchronization) and temporal intensity (qualitative temporal synchronization) in real-time occurring actions. The scales of temporal density in an action would then influence the subjective experience of time as fleeting, dragging, intense, or subtle.

Sigrid Norris (2004) proposes that all social actions are multimodal. This argument could be expanded by suggesting that multimodality arises not only from ever-interacting *systems of representation* (Kress & van Leeuwen, 2001) but, more so, from the tendency of actions to temporal complexity. Along these lines, Norris (Norris & Jones, 2005; Norris, 2009) conceptualizes the idea of *frozen actions*, which collapse linear real time of actions into a historified (Bourdieu, 1972/1977) expression or an artifact, thus capturing past and present in a single, objectified moment. With this concept, Norris acknowledges the presence of past actions in present cultural tools, which themselves afford and constrain present and future actions—but also allow for reflexive recontextualization of past events. Thus, the frozen action of carving wood, for example, which becomes objectified in a hand-made table or chair, may resemiotize woodcarving as a form of artistic creation of a piece of lifestyle furniture rather than a utilitarian production of an everyday object. Accordingly, the semiotic meaning of the action of carving wood not only defines the object it creates but, reversely, is just as defined by these objects.

Such observations about temporality in social actions—Bakhtin's chronotopes, Lemke's heterochrony, Scollon's pacemakers, Norris's frozen actions and Frommherz's temporal density—are significant to multimodal analysis as they suggest actions to be inherently dynamic and polytemporal, and equally show a capacity for an anachronistic embedding of actions and processes in their subsequent material expressions. The multimodal perspective on time in actions acknowledges how past events, present actions, and forward-directed intentions intersect at any one moment in the flow of a social practice.

Recognition of the multidimensionality of time in social actions can also be found in earlier investigations of primary human behavior. The cultural theorist Johan Huizinga (1872–1945) suggests that experience of time in play is inherently multimodal—a lived moment with all senses of the player immersed in present activities while transcending time and space. When in play, Huizinga (1938/1955) argues, the senses are fully engaged and focused, time is suspended and space dissolved. While Huizinga maintains that play is principally distinct from ordinary activities, he nevertheless suggests that play is central

to human social behavior: Play would be a fundamental feature of life and primary to culture. If so, play may be considered the “mother of all social actions,” and human activity might enact a faculty for transforming space and time whenever a purposeful and focused action is performed. The psychologist Mihaly Csikszentmihalyi (1992) draws on Huizinga when he discusses *flow* in human engagement. Flow, according to Csikszentmihalyi, synchronizes actions and awareness, and focuses attention on all elements of the present activity while suspending irrelevant outside stimuli. Flow involves temporal synchronization of multiple communicative modes, causing the mind to focus and to fully immerse into the activity. It might be this single-mindedness during flow activity that alters the actor’s sense of time, often rendering time faster while in action and longer, or richer, in memory thereafter.

Equipped with an increasing understanding of time as a phenomenon of enactment, multimodality provides a key tool to analyzing qualitative temporality not only in social actions but also in cultural artifacts. Temporality in music, for instance, arises from a synchronization of the metric cycles of beat, tempo, and rhythm in order to achieve an aesthetic experience of sound. Without such temporal synchronization, sounds would be perceived as little more than noise. Much contemporary music increasingly considers multimodal aspects in both composition and “consumption” of music. Stage performances today sometimes place musicians elsewhere than on the stage, and such spatially dispersed positioning of audio sources influences not only compositional thinking but also the aesthetic experience in the listener. The emerging field of psychoacoustics concerns itself with the space, movement, and directionality of sound, which involve not just the human sense of hearing but also those of proxemics, spatial perception, kinesthesia and proprioception (see Jeffress, 1948; Blauert, 1983; de Gotzen, 2004). Especially by means of electroacoustic technologies that allow real-time processing of sounds, new listening dimensions in multimodal environments can be explored. In a more populist application, modern karaoke systems deploy multimodal channels to extract lyrics from the original audio, visually segment them into singing phrases, and display these in real-time coloring on the karaoke video screen (see Zhu, Chen, & Sun, 2005). The auditory experience of the performer is thus visually enhanced and supported in real time.

In multimedia and cinema, temporal synchronization also occurs between audio and visuals. Michel Chion (1994) highlights the importance of an immediate relationship between sound and image achieved through *synchresis*, a neologism that merges “synchronize” and “synthesis.” The term “synchresis” emphasizes that temporal synchronization does not simply afford cultural tools or communicative modes to concomitantly overlap but rather achieves a full amalgamation, a merging into an instance of unity. Traditional cinema, considered a time-based medium ever since it began, routinely manipulates its narratives via a great repertoire of stylistic techniques, and does so very successfully despite the strictly linear layout of sequenced images. Paul Ricœur (1984) calls upon a *configuration of time* that creates a story beyond mere sequencing of events. The story takes a temporal shape, creates a pattern, a narrative sense, out of successive moments. Artistically created temporality in film is a key feature of the medium to the extent that entire film genres are dedicated to their temporal particularities: The developmental film, action movies, and the epic are just some examples. In newer audiovisual formats, such as the music video, the classic position of audio as *added value* to the image (Chion, 1994) submits to a new role of audio as a temporal baseline (or counterpoint) along which a play of imagery unfolds (see Vernallis, 2004). In this sense, music video can be understood as *multimodal music* rather than an audiovisual format. In the music video, sound takes the lead role and determines the overall aesthetic experience of the piece, often achieved through particular camera moves and editing techniques. Visuals may be discursive to the audio but they do not intend to tell a cohesive story. Narrative flow yields a multimodal rhythmicity, a

multisensory experience of aesthetically congruent, harmonized time. A narrative, if there is one at all, is neither explicitly nor implicitly extant in the music video but emerges—it is created by the viewer at the moment of multimodally engaging with the artifact (see Bakhtin's understanding of the "event" above). This way, the narrative in music video, at least in significant parts, moves into the realm of personalized experience that is often based on subjective interpretation, personal preferences, and individual appreciation of the artifact and its intertextuality.

These and other studies suggest that time, be it continuous or discrete, linear or cyclic, finite or eternal, symmetric or asymmetric, provides a multimodal experience in the social action and the cultural tools that it employs. With an increasing number of studies into the temporality of multimodal communication, the epistemology of time may have just started to consider human actions as a point of reference to an understanding of time apart from the historic, and rather impenetrable, concepts of eternity and death.

Multimodality in Corporate Communication

CARMEN DANIELA MAIER

Multimodal texts making meaning in multiple semiotic articulations and multimedia contexts are central in contemporary corporate communication. Iedema acknowledges that “the extent to which formal bureaucratic and corporate organizations have adopted multimodal ways of (self-) representation is remarkable” (Iedema, 2003, p. 38). Any single corporate communication employs many semiotic modes in complex combinations, beyond, for example image-text or moving image with text.

Among the most important factors that have contributed to this development in contemporary corporate communication strategies are the greater fragmentation and identity renewal of consumer groups and the development of technology. It should be acknowledged from the very beginning that these two factors cannot be separated from each other because they are in a continuous interdependent relationship. Cornelissen discusses the environment in which corporations have to communicate today and he recognizes that consumer groups are “more fragmented and less homogenous than before” and therefore corporations “have to use more channels and different media to reach them” (Cornelissen, 2008, p. 24). Furthermore, these contemporary consumer groups are characterized not only by less homogeneity; they are also multiliterate consumers who have acquired and continue to develop multimedial and multimodal communicative expertise, needs, and behavior. In order to meet the expectations of existing and prospective multiliterate consumers, corporate communicative strategies have to keep pace with the development of the newest digital technologies that give unlimited and immediate access to dynamic and borderless groups of multiliterate consumers. Therefore, the advance of technology and especially the globalization of (multi)media have also tremendously affected multimodal communication in corporate contexts.

It would thus be of interest to see the consequences of these relentless communicative challenges from corporate contexts upon the choice of topics in multimodal research. From print and television advertisements, product manuals, Web sites to multimedia resource kits and multimedia franchises, the various corporate communication materials and phenomena have attracted the attention of multimodal researchers during the past two decades. Both the exploration of their complex semiotic structures, communicative purposes and contexts, and the development of adequate theoretical frameworks and concepts have been in focus. Multimodal research has addressed the effects of (global) technology on the renewal of well-known corporate communication materials like advertisements and the emergence of new corporate communication phenomena like multimedia franchises. It has also addressed the impact of multimodal and multimedial communicative strategies upon the identity of consumers and the processes of specialized knowledge communication. The relationship between multimodality as technology of representation and multimediality as technology of dissemination has also caught the attention of researchers analyzing corporate materials and phenomena. Of particular interest is also the research work focused on methodological models for multimodal transcription of complex corporate texts and multimodal concordancing.

2 MULTIMODALITY IN CORPORATE COMMUNICATION

Advertisements are among the multimodal corporate texts that have generated the widest interest in multimodal research. Kress and van Leeuwen (1996), Thibault (2000), Machin (2007), Machin and van Leeuwen (2007), and Stöckl (2004) are among those who have approached the analysis of advertisements giving detailed accounts on both changing semiotic landscapes and the intersemiotic links that are specific to these corporate texts. Changes in the contemporary semiotic landscape are addressed by Kress and van Leeuwen who employ the concept of “design” in order to explain how various modes and media are selected in different communicative practices and how communicative acts are “signified in these various modes” (Kress & van Leeuwen, 2001, p. 120) in advertisements and product catalogs. They analyze the communicative practices and especially the use of modes linked to these types of corporate materials and find that “advertising often seeks to address its audiences as unique individuals, rather than as groups of people with conforming consumption patterns which they really are” (Kress and van Leeuwen, 2001, p. 122). Stöckl concentrates also on the use of semiotic modes in his multimodal analyses and he derives a system network of modes showing that each mode can be categorized according to its semantic potential, semiotic properties, and cognitive orientation. He points out that “creators of ads exploit the whole range of semantic, formal and pragmatic relations, which can be anything from simple to complex” (Stöckl, 2004, pp. 21–2) when they link modes like language and images. The concept of “resemiotization” offers Iedema the possibility to expand the multimodal approach and to explain how and why certain modes are employed for certain communicative purposes at certain times. In his multimodal analysis, he shows how the new user-oriented ethos in Apple computer manuals motivates a shift in their communication from linguistic to visual representation. This shift also facilitates a closer semiotic resemblance of the computer manuals with the brochures that present a range of Apple products for sale. Iedema also mentions annual reports, newsletters, and brochures among the multimodal corporate texts in which “the renegotiation of what different semiotics are made to do” (Iedema, 2003, p. 38) takes place due to new (multi)media designs.

Significant research in the field of multimodality has been devoted to the investigation of multimodal texts and “intertexts” (Lemke, 2009, p. 140) in corporate (multi)media contexts. Researchers concentrate their multimodal investigations in these contexts on issues related both to the global aspects of (multi)media and to consumers’ identities. Van Leeuwen (2005) and Machin and van Leeuwen (2007) use methodological tools belonging to genre, layout, and modality analysis in order to explore the multimodal communicative strategies in advertisements of global corporate media. Analyzing versions of *Cosmopolitan* magazine which have appeared in several countries, they demonstrate that, in order to persuade consumers, global corporate media exploit general and flexible genres and formats deliberately transcending cultural differences while pretending to address local environments. In spite of the use of local languages and specific multimodal constructions, the ideology, values, and identities of the magazine pervade the multimodal discourse of all the advertisements and the other texts in the magazine’s localized versions because “corporate media are driven by advertising revenue and must present a world that is in harmony with the message of advertising” (Machin & van Leeuwen, 2007, p. 170). In their work, Machin and van Leeuwen arrive at the conclusion that global media formats are crucial in aligning practices and values with the consumption of goods and services, and in fostering “new lifestyle identities” (Machin & van Leeuwen, 2007, p. 171).

Lemke transcends the analysis of print advertisements and he investigates the phenomenon of transmedia franchises by exploiting the complementarity of semiotic and phenomenological approaches. Meant to advertise a fictional world, “books, and films, and websites, and games, and a wide variety of merchandise” (Lemke, 2009, p. 145) are linked in transmedia franchises. Lemke explores transmedia franchises like those of *Harry Potter*, *Lord of the*

Rings, *Star Wars*, and others, and he shows how the designs of the franchise producers are complemented and extended by the consumers' interpretations and expressions which appear in fan-produced and fan-maintained discussion forums, videos, Web sites, and other multimodal texts. Underlining the importance that should be given to the analysis of all these texts, he also highlights the idea that contemporary global corporations market specific identities:

It has long been a commonplace of critical media analysis (Williamson, 1978) that advertising media sell not just products and services but lifestyles and ideologies. Today we can say that they sell identities: identities which imply dispositions to buy some kinds of products and services rather than others. (Lemke, 2009, p. 150)

Aspects of changes in consumers' identities and roles are also discussed by Maier (2008a, 2008b) in the analysis of complex corporate materials that are distributed to professionals, educators and students in order to communicate specialized knowledge while advertising specific products and services. Analyzing Kodak's multimedia resource kits, Maier explains how a "packaged resource kit" (Kress, 2001, p. 65) like a DVD inserted in a booklet with links to a company's Web site makes specialized knowledge available through more than one medium at a time and it also transforms the consumers' identities and roles. They are given active roles as they are not supposed to merely read the booklet and see the DVD, but to use the kit in different ways in class or on location according to their needs and expertise. Furthermore, the consumers are implicitly made aware of the fact that their identity as the next generation of film and video experts depends on buying and using the advertised products. In order to succeed to communicate these identities and roles, Kodak's multimedia materials are characterized by a multimodal mixture of argumentative and instructive discourses. This combination of instruction and argumentation also influences the communication of specialized knowledge: "In the case of corporate interactive materials, the boundaries between types of knowledge like *know-what* and *know-why* types might be blurred due to the fact that the instructive purposes are continually combined with the persuasive ones" (Maier, 2008b, p. 114). For example, one of Kodak's multimedia resource kits conveys specialized knowledge about film and video through a series of testimonials. Renowned figures in the film business present their perspectives upon the advantages and disadvantages of film and video technologies, while their opinions are visually exemplified through excerpts from their works. Through a multilevel analysis, Maier demonstrates how both the instructive and the argumentative discourses are coded in the generic frame of the multimodal testimonials. Simultaneously,

the shots and stills from different films, documentaries or sitcoms not only display visually the exemplary achievements of the experts in a persuasive way, but they also complement the detailed instructive discourse carried by the verbal mode. At the same time, the instructive effect of those shots and stills that witness highly professional expertise is complemented by verbal arguments. (Maier, 2008a, p. 94)

It would seem that buying the advertised Kodak product(s) is a prerequisite for fully benefiting from the amount of specialized knowledge persuasively communicated in the testimonials.

Due to the complexity of all these texts, intertexts, and multimedia resource kits, multimodal research has also been focused on methodological and theoretical aspects of multimodal transcription and concordancing practices. Thibault proposes a static transcription model that distinguishes in detail the wide range of meaning making resources deployed in television advertisements, and establishes the criteria for explaining how and

why these resources co-contextualize each other (Thibault, 2000, p. 312). According to Thibault, capturing all the semiotic resources and their interplay in detailed transcriptions allows multimodal researchers to reconstruct the advertising message at several levels as the text flows in time. Applying the model to the transcription of a television advertisement offers Thibault the possibility to show how the television advertisement of a banking corporation constructs a corporate national identity founded on national myths and archetypes.

In parallel, multimodal research also devotes considerable attention to the development of online computer-assisted tools for storage, retrieval, and comparative analyses of multimodal corporate texts in order to account for recurrent patterns of meaning and generic structures (Bauldry, 2005).

Lemke acknowledges the theoretical and methodological challenges that face future multimodal research when he addresses the phenomenon of complex media franchises:

Our encounter with these media is not simply a trajectory through a single coherent work. It is a traversal across the boundaries between works, media, genres, sites, institutional contexts, activities, etc. (Lemke, 2005). And along such a traversal we are constructing and cumulating across timescales *transmedia meaning effects* which do not occur within single works, or between intertexts in the same medium, or indeed within the scope of any theory of meaning-making or multimodal analysis that exists today. (Lemke, 2009, p. 145)

Without downplaying these challenges, it should be recognized that corporate communication with its multimodal complexity offers incomparable research opportunities. Unlimited and immediate access of corporations and consumers to new multimedia, the renewal of consumers' identities, corporate media globalization, and the continuous changes in semiotic landscapes and specialized knowledge communication are among the latest multimodal research topics. As shown, multimodal research has continuously stretched the theoretical and methodological frontiers of its concerns when confronted with these dynamics of corporate communication phenomena. It is obvious that it will continue to do so, keeping pace with the continually renewed corporate communicative strategies employed to inform, persuade, and entertain the new generations of multiliterate consumers.

Multimodality in Workplaces

RICK IEDEMA

In recent times, applied linguistics has broadened its analysis from language to include meaning-making phenomena other than language. This broader perspective has been labeled “multimodality” (Kress & van Leeuwen, 2001). Multimodality acknowledges that discourses and practices frequently mobilize, besides language, embodied gestures and actions (Martinec, 2000), visual resources (Kress & van Leeuwen, 1996), music and speech sound (van Leeuwen, 1999), and spatial constructions and building-internal designs (O’Toole, 1994). An important advance in making sense of our increasingly complex social world, multimodal analysis enables us to account for how people negotiate the growing array of media and technologies that they draw on in their interaction and communication.

In the case of the workplace, applying a multimodal lens is important to understand the constantly changing practices and discourses at work. It is clear that human work is not as repetitive and mechanical as it used to be in the past. Repetitive activities tend to be relegated to machines. Besides monitoring and maintaining the work done by such machines, human activity focuses more now on dealing with rapidly changing social, organizational, and industrial circumstances. In doing so, human activity in the workplace is increasingly adaptive, exploratory, and inventive, either to realize or to achieve innovations. This is talked about using specialized labels such as “knowledge development,” “practice improvement,” and “productivity enhancement.”

The innovations employees are expected to produce and enact in the workplace manifest in two ways. First, innovation comes into play with the process of translating aspects of here-and-now activity into, for example, guidelines, protocols, or technological (machine) replacements of humans (Iedema, 2001). In capturing and technologizing “what works,” innovation helps turn here-and-now activity into durable and standardized forms and formats. Strikingly, this conversion into durable, standard forms and formats mirrors a conversion that takes place at the level of organizational language itself (Iedema, 1997). There, we find many formulaic descriptions of work, typified as manuals, standards, protocols, and so forth. Formulaic descriptions are particularly prominent in bureaucratic, administrative, and managerial discourses. Linguistically, such discourses come about by recasting how we describe organizational activity from “doing” forms such as “employees are resigning due to burnout,” into “thing-like” forms such as “attrition” (Martin, 1993). Similarly, “To whom it may concern” exemplifies the formulaic, standardized, and object-like character of discourses whose purpose is to regularize and regulate employee conduct. This “thing-ification” or standardization of discourses and practices is at the heart of workplace organization. Without it, industrial and service productivity would not have reached the levels of intensity and efficiency it has.

However, in the 21st century a new workplace characteristic is coming to the fore. Contemporary organizations are shifting into flexible production in the search for product uniqueness. This search is reflected in much restructuring, retraining of employees, and redesigning of positions, relationships, and roles. Such changes have now become the norm. Not changing is no longer a viable business option, not even for public service organizations. Indeed, change has become a resource in and for itself, a way of identifying the organization, its achievements and its commitment to improvement (Thrift, 2005). The

pursuit of change is now deeply embedded in workplace practices such as project employment, practice improvement, and flexible production (Castells, 2000).

Since work is now both about change and subject to change, many workplace discourses and practices are temporary (Iedema & Scheeres, 2009). The impact of this temporary nature of workplace practices and discourses on employees is that people have to spend extra effort and time on rethinking and redesigning work processes and tasks, as well as occupational and professional relationships. Employees are granted a growing range of resources and media to do this. Many of these resources and media are available in the digital, web-based environment, of course, offering everything from graphic document design to public presentation software that accommodates moving visual components, sound, and video. Concomitantly, employees' literacy skills have shifted in recent times from being largely paper-based to becoming overwhelmingly digital media-based.

These developments have in turn created considerable boundary blurring between what used to be identifiable roles and ranks: "even factory workers are said to require interpersonal and decision-making skills previously reserved for managers" (Barley & Kunda, 2001, p. 77). This skill expansion is critical for employees to participate in the contemporary workplace. It enables them to demonstrate current knowledge of and commitment to the changes and innovations that permeate work. Indeed, the ability of employees to display up-to-the-minute knowledge and renewed commitment is critical to being and remaining a "contemporary" employee. Ongoing skill expansion enables employees to show that they have a willingness to learn. It shows they are not only sufficiently flexible to fit in with organizational change deemed to add to productivity and practice improvement, but that they will contribute to initiating and promoting change.

These evolving characteristics of workplace practices and discourses are of special interest to the applied linguist. A critical concept here is "knowledge work" (Drucker, 1993). Knowledge work is evident in the increasingly wide-ranging and probing reporting and monitoring functions of employee practice. Examples are work plans, project reports, and process evaluations. From an applied linguistics perspective, knowledge work operates at the interstice between existing standardized workplace discourse such as regular reporting and information filing, and forward-looking, innovative discourse such as plans, designs, and proposals.

The second characteristic of analytical interest is the intensification of "emotional labor" in the workplace (Hochschild, 1983). Emotional labor refers to the interpersonal energy that employees put in play at work. This energy defines contemporary forms of work. It comes into play with processes, roles, and tasks that are no longer linear and predetermined, but exploratory, change-oriented, and subject to testing and redesign due to organizational arrangements generally being too temporary to offer people lasting positions and well-defined career trajectories (Castells, 2004). As people's tasks, positions, and careers lose structure, homogeneity, and predictability, the emotional energy they expend on forging and maintaining a feasible workplace identity—or even identities—becomes more intense.

Employees' work affiliations and team configurations may be short-lived. Workplace relationships require ongoing adjustment and regeneration, leading in some cases to mental distress and burn-out for those unable to "keep up" (Zapf, Seifert, Schmutte, Mertini, & Holz, 2001). Apart from typifying service–consumer relationships, emotional labor also is manifested in workplace meetings. There, in spaces away from the machine, the service counter, and the work desk, employees perform their knowledge and commitment in discourses that enhance practice, raise productivity, strengthen the service profile, learn from incidents and complaints, and propose new collaborations and processes to resolve remaining problems and capitalize on new opportunities.

Being Open

Communicating with patients, their families and carers following a patient safety incident

Being open is a set of principles that healthcare staff should use when communicating with patients, their families and carers following a patient safety incident in which the patient was harmed.

Being open supports a culture of openness, honesty and transparency, and includes apologising and explaining what happened.

In 2005, the National Patient Safety Agency (NPSA) issued a Safer Practice Notice advising the NHS to develop a local *Being open* policy and to raise awareness of this policy with all healthcare staff.

The guidance has now been revised in response to changes in the healthcare environment and in order to strengthen *Being open* throughout the NHS.

The revised *Being open* framework (available at www.nrls.npsa.nhs.uk/beingopen) should be used in conjunction with this Alert to help develop and embed *Being open* in each NHS organisation.

The *Being open* principles are fully supported by a wide range of royal colleges and professional organisations, including the Medical Defence Union, Medical Protection Society, NHS Litigation Authority and Welsh Risk Pool.

Tools to support organisations in the implementation of this Alert are available at: www.nrls.npsa.nhs.uk/beingopen

1997 November 2009

Action for the NHS

For action by Chief Executives of organisations commissioning and providing healthcare.

Deadlines:

- Actions underway:
22 February 2010
- Actions completed:
23 November 2010

Actions:

- 1) **Local policy:** Review and strengthen local policies to ensure they are aligned with the *Being open* framework and embedded with your risk management and clinical governance processes.
- 2) **Leadership:** Make a board-level public commitment to implementing the principles of *Being open*.
- 3) **Responsibilities:** Nominate executive and non-executive leads responsible for leading your local policy. These can be leads with existing responsibilities for clinical governance.
- 4) **Training and support:** Identify senior clinical counsellors who will mentor and support fellow clinicians. Develop and implement a strategy for training these staff and provide ongoing support.
- 5) **Visibility:** Raise awareness and understanding of the *Being open* principles and your local policy among staff, patients and the public, making information visible to all.
- 6) **Supporting patients:** Ensure Patient Advice and Liaison Services (PALS), and other staff have the information, skills and processes in place to support patients through the *Being open* process.

The above helps explain why the analysis of workplace discourses and practices has changed focus. In the past, applied linguistic analysis of workplace practices and discourses could safely separate linguistic phenomena from other, multimodal dimensions of meaning making. Discourses and practices were relatively stable. Ways of writing texts such as memos, policies, and annual reports were largely prearranged. There were in-house etiquettes governing the semantics and syntax of such documents, and they tended to make little use of visuals and other nonlinguistic resources. Today, workers draw on a much wider range of meaning-making resources and practices for doing their work, many of which are digitally mediated (Iedema, 2003). The analysis of workplace discourses and practices therefore requires a multimodal perspective.

Consider the “Patient Safety Alert” shown as an example (see Figure 1) of how the contemporary workplace requires employees to communicate more intensely in face-to-face situations, and to produce more written documentation, from form filling to report writing. The alert is an example of a contemporary organizational memo that makes use of various meaning-making resources. Unlike its predecessors, the alert presents a sophisticated design arrangement, reminiscent of an advertisement. It divides the page into five discrete spaces, each doing very different discursive work. Its title, “Being Open,” is in over-size font; it comes across as a title one might find on the front cover of a novel, and it has a distinct color.

These and other features show the “Being Open” alert to exemplify the trends discussed above. The speed of practice change is apparent from the “Deadlines” statement, alerting NHS staff (“NHS” is the acronym for the National Health Service, the UK’s public health-care system) to the dates that govern what they are expected to do, and from the statement that this alert replaces a previous alert, bottom left. The knowledge work is evident from employees being expected to write the “Being Open” principles into their organization’s policies, role definitions, and responsibility statements. Emotional labor is inscribed into the very conduct that the “Being Open” policy advocates. Rather than portraying clinical errors as “inevitable clinical complications,” as has been common practice to date, clinicians must now openly and honestly disclose and apologize for unexpected outcomes and errors in patients’ care. These organizationally mandated conducts embody and incur considerable emotional work.

Applied to the “Being Open” alert, multimodal analysis provides a twofold lens. First, it enables analysis of regular and standardized workplace forms and formats. The alert provides a prime example of how a modern-day government service organization expresses its directives—that is, ways of telling others what to do. It frames imperatives as “actions,” and it arranges these “actions” spatially, on the far right of the document, a visually prominent position. It also deploys up-to-date document design, combining symbols denoting urgency (the red and the road sign used top left), acceptability (the green and the pleasant arrangement used for “Being Open,” in addition to its newsy font), and efficiency (the column spacing, the numbering of actions).

Second, multimodality sheds light on the constancy with which employees renegotiate and redesign workplace practices and discourses. That is, multimodality enables us to capture how and how often employees translate and transform what they do, say, and write (Iedema, 2001). Thus, with reference to “Being Open,” a multimodal perspective highlights differences with more conventional “to/from/date” memos and the ways they used to frame directives and visualize their importance and urgency. Multimodality draws attention to how linguistic meanings are increasingly recast as visual meanings. The alert shown above no longer uses the conventional memo language and headings, drawing instead on a new generation of policy discourses and policy implementation practices (Jorm, Banks, & Twohill, 2008). Multimodal analysis shows how some conventional meanings drop away to make room for new ones, transferring traditional forms of delegation (“to/from/date”) into new ones (e.g., “Action for the NHS”).

In sum, multimodal analysis complements linguistic analysis in our effort to map how workers invent new roles, designs, and tasks. Linguistic analysis captures how workers shunt back and forth between situated, here-and-now talk and formalized there-and-then representations. The analysis of work interaction targets how employees mediate and negotiate their personal, practical, and ideological differences into local agreements and time-limited plans. It shows how employees move toward different formal, durable, and standardized kinds of meaning making that background disagreements and embed new personal alignments and viewpoints. It provides a lens on how new authoritative meanings come about and are shaped and reshaped as rules and truths, visually, spatially, or linguistically.

By targeting the rapidly shifting trends in workplace practices and discourses, multimodality does not limit itself to a particular type of representation (e.g., language), or mix of representations. Its interest lies in analyzing the interface between the persistent features and the changeable dimensions of organizational knowledge and relationships, enabling multimodality to shed important light on how employees manage the ongoing production and reproduction of workplace discourses and practices.

Multiple Regression

YONG-WON LEE

Introduction

Multiple regression is a statistical technique used to examine which among independent variables are related to a dependent variable, and to explore the forms of the relationships between these variables. Multiple regression can also be used to predict scores of a dependent variable based on the scores of a set of independent variables. An applied linguistic researcher may have some theoretical relationships hypothesized a priori between a dependent variable and a set of independent variables (e.g., between English as a second language [ESL] students' reading proficiency and a set of predictor variables, such as years of English-language study, aptitude, motivation, gender, etc.). In such a case, multiple regression analysis can be used not only to test or confirm such theoretical relationships among the variables but also to predict someone's ESL reading score given his or her scores on a set of independent variables.

Generally speaking, regression is a method of explanation and prediction in scientific research. Unlike in simple regression involving only one independent variable, there are two or more independent variables involved in multiple regression. One primary goal of multiple regression, in addition to score prediction, is to find the *best-fitting, most parsimonious* statistical model that describes a relationship between the dependent variable and a set of independent variables of interest. This usually requires the comparison of multiple, competing models in terms of their explanatory power and the evaluation of the unique contribution made by each independent variable to the models.

As in the case of ESL students' reading proficiency represented by an Internet-based Test of English as a Foreign Language (TOEFL iBT) reading scale score, the dependent variable will mostly be a continuous variable. However, applied linguistic researchers often have to deal with dependent variables that are not necessarily continuous or normally distributed, such as students' pass/fail outcomes on an English teacher certification test (binary), students' speaking scores based on a 5-point scoring rubric (categorical), and frequencies of a particular lexical item or word combination in an English learner corpus (count). Each of these different research contexts requires a different type of multiple regression.

Multiple regression analysis can also be classified into three different types based on the nature of the dependent variable being examined: linear regression, logistic regression, and Poisson regression. In linear regression, the dependent variable is assumed to be continuous, whereas it is categorical (or discrete) in logistic regression. Logistic regression is used when the dependent variable is categorical while the independent (explanatory) variables are categorical, continuous, or a mixture of both. Logistic regression can further be subdivided into logistic regression for a dichotomous dependent variable and logistic regression for a polytomous dependent variable. The dependent variable is binary (or dichotomously scored) in the dichotomous model, whereas it is polytomously coded (with more than two response categories) in the polytomous model. Poisson regression is the most appropriate method when the dependent variable is count data with a Poisson

2 MULTIPLE REGRESSION

distribution. When the Poisson regression is applied to contingency tables, it is often called a log linear model.

Recently, a family of regression models, including linear regression, logistic regression, Poisson regression, analysis of variance (ANOVA), and other related models, have been unified into a single statistical framework of generalized linear models (GLMs). GLM generalizes linear regression by allowing the linear model to be related to the dependent variable via a so-called “link function” and use the maximum likelihood method in the model fitting process (Agresti, 2002, 2007). This has made it possible to recast logistic regression and Poisson regression models in the framework of linear regression.

In this entry, our discussion will be focused on simple linear regression, multiple linear regression, multiple logistic regression for a dichotomous dependent variable, and multiple logistic regression for a polytomous dependent variable, not only in their unique form but also in their GLM equivalents.

Linear Regression

A linear regression model describes a relationship between the value of an independent variable (simple regression), or the values of a set of independent variables (multiple regression) and the expected value of the dependent variable, or the corresponding conditional mean of the dependent variable.

Assumptions

In linear regression, the dependent variable is basically continuous and assumed to have a normal distribution. Linear regression is based on several other important assumptions (Henning, 1987; Reinard, 2006). First, it is assumed that both the independent and dependent variables are linearly related among themselves. Second, the prediction error (or residual) is assumed to be a random variable, with a mean of 0 and conditional on the independent variables. This also means that the errors should be uncorrelated. Third, the variance of the error is assumed to be constant across observations, which is often called the assumption of *homoscedasticity* in the literature. Fourth, in the case of multiple regression, the independent variables must not be linearly dependent or highly correlated, which also means the absence of *multicollinearity* among the independent variables.

When these assumptions are violated, the estimated parameters will become meaningless and thus it would be very difficult to generalize the findings to the population. When there is a minor violation, then many of the estimated parameters and inferential statistics associated with them can still be considered to be robust. There also are ways to fix some of these problems. When multicollinearity exists between two independent variables, for instance, the independent variables that are highly correlated can be collapsed into a single variable or one of the two variables can be dropped from the regression.

Correlation and Simple Regression

Although simple linear regression is not much used in applied linguistic research, it is important to grasp the basic structure of, and the related concepts associated with, the simple regression model and its relationship with correlations in understanding multiple regression. *Correlation* is a measure of association between two variables, which allows us to investigate the strength of their association. One limitation of correlation, however, is that the variables are not designated as dependent or independent, and thus it is not possible to make a prediction of one variable based on another. However, linear regression allows us to make such a prediction by estimating the best straight line (or a regression line) summarizing the association between the variables on a scatterplot.

A regression model attempts to describe the relationship between the values of two variables in the form of a mathematical equation. The regression line is a plot of the expected value of the dependent variable for all values of the independent variable. The regression line is the one that best fits the data on a scatterplot or, technically, the line that minimizes the sums of squared residuals (the difference between expected and observed scores) on the dependent variable.

In simple linear regression, we predict scores on a dependent variable based on the scores of a single independent variable. A simple linear regression model (with the error component included) can be presented in the following equation (Judd & McClelland, 2001):

$$Y_i = \beta_0 + \beta_1 X_i + \epsilon_i \quad (1)$$

where Y_i represents a dependent variable

X_i represents an independent variable

β_0 is an intercept parameter

β_1 is a slope parameter associated with the dependent variable X_i

ϵ_i represents an error.

In this case, the right side of the equation consists of two main components, which include a regression model ($\beta_0 + \beta_1 X_i$) and the error (ϵ_i). There are two parameter values to be estimated for the model: the intercept parameter (β_0) and the slope parameter (β_1). The intercept is also called the constant. The intercept is the point on the y -axis at which the regression line crosses. In other words, the intercept parameter tells us the value of Y_i when X_i equals zero. The slope of the regression line indicates the steepness of a line. The slope parameter (β_1) tells us about how much change there will be in the dependent variable when there is a one-unit change in the independent variable X_i . Because the regression model is not usually a perfect predictor of score on the dependent variable, there is also an error term in the equation (ϵ_i). The error (ϵ_i) is defined to be the difference between the observed (Y_i) and predicted values of the dependent variable ($\hat{Y}_i$), which is often called a *residual*.

There is an important link between the correlation coefficient and the slope parameter. The correlation coefficient is the slope of the regression line in simple regression, if both the independent and dependent variables are measured in standardized z scores (Henning, 1987; Reinard, 2006). Because of such a link between the two, the coefficient of determination (or R^2) can prove very useful in regression. The coefficient of determination is the squared value of the correlation between the independent variable and the dependent variable. Its value may vary from zero to one. The R^2 value can also be interpreted as the proportion of variance in the dependent variable that is explained by an independent variable (or the regression model). The interpretation of the R^2 value becomes a bit more complex in multiple regression, which will be discussed later.

Multiple Linear Regression

In multiple regression, we expand the basis of our prediction by using more than one independent variable in our regression model. In multiple regression, we consider not only a full regression model with all possible independent models included in it but also the reduced models with smaller sets of independent variables. For our final model, we can select a model that is most parsimonious and also best fitting through a process of model comparison. The magnitude and sign of the estimated slope parameter value for each of the independent variables, along with the intercept variable, will help us to examine whether or not a certain independent variable has a unique explanatory (or predictive) power for the dependent variable and, if so, how strong the predictive power is.

4 MULTIPLE REGRESSION

In multiple linear regression, the relationship between the variables is assumed to be linear. A multiple (linear) regression model can be presented in the following equation:

$$Y_i = \beta_0 + \beta_1 X_{1i} + \beta_2 X_{2i} + \cdots \beta_m X_{mi} + \varepsilon_i \quad (2)$$

where Y_i represents a dependent variable

X_{1i} represents the first independent variable

X_{2i} represents the second independent variable

X_{mi} represents the m th independent variable

β_0 is an intercept parameter

β_1 is a slope parameter associated with the dependent variable X_{1i}

β_2 is a slope parameter associated with the dependent variable X_{2i}

β_m is a slope parameter associated with the dependent variable X_{mi}

ε_i represents an error.

In multiple regression, the slope parameter associated with β_1 tells us about how much change there would be in the dependent variable when there is a one-unit change in the independent variable X_1 given the fixed values of other independent variables. The statistical significance of the intercept and the slope parameter for each of the independent variables can be tested through t statistics (Reinard, 2006). The t statistic for the significance of the slope is designed to test whether the slope parameter is significantly different from zero. If the slope parameter is zero or not significantly different from zero, knowing the value of the independent variable will not improve our ability to predict the dependent variable. Some researchers prefer to report the F ratio, which is equal to the t statistic squared, instead of the t statistic.

In multiple regression, as in other statistical prediction models, there are two important goals that are inherently in tension: (a) reducing prediction error as much as possible and (b) keeping the model as simple (or parsimonious) as possible (Judd & McClelland, 2001). The first goal has to do with finding an optimal set of independent variables that makes the best prediction of the values on the dependent variable. This means that we should minimize the errors of prediction or maximize the amount of variance explained in the dependent variable. This can usually be achieved by adding more explanatory (or independent) variables to a regression model.

An equally important goal of regression analysis is to find a statistical model that describes a relationship between a dependent variable and a set of independent variables in the *most parsimonious* way. This means that, whenever a more complex (or augmented) model is created by adding more independent variables to a simpler (or compact) model, each of the newly added variables should be evaluated in terms of its unique contribution to the predictive power of the regression model. A comparison between a compact model and an augmented model is made to evaluate the significance of the increased explanatory (or predictive) power of the model due to the newly added variables.

R^2 is basically a measure of the goodness of fit of the linear regression model. This can also be used as a useful measure of effect size for a newly added variable in multiple regression. Since the prediction model includes more than one independent variable in multiple regression, the interpretation of R^2 in multiple regression, particularly for the additional independent variables, should be analogous to that of partial correlations. Partial correlation is a correlation between two variables, while controlling for the effect of additional variables. By the same token, the increase in R^2 due to a newly added, independent variable in multiple regression represents the proportion of the variance in the dependent variable which is additionally explained by the newly added variable. Adjusted R^2 , which is often reported in literature, is a modified version of R^2 . One advantage of adjusted R^2

is that it increases only if the newly added term improves the regression model more than would be expected by chance.

Another important thing to be mentioned in regression modeling has to do with model selection strategies. There are two major ways to select a final set of independent variables: forward and backward selection. Forward selection involves starting with no variable in the model and then adding the variables one by one, using a variable that has the highest correlation with the dependent variable as a starting point. Whenever a new variable is added, a test can be conducted to check whether a newly added variable can significantly increase various criterion indices, including the R^2 and adjusted R^2 values. On the other hand, backward selection involves starting with all candidate variables included in the model (the maximum or full model), dropping any variable that is not significant. Nowadays, there is an automatic variable selection algorithm in place which is called stepwise regression. Stepwise regression employs a special kind of forward selection in which all variables are tested if their contribution is significant after a new variable is added. For this reason, an already selected variable can be eliminated in stepwise regression.

Logistic Regression

Logistic regression is usually used to predict the probability of occurrence of a *binomial* or *multinomial* event by fitting the data to a logit function logistic curve. In logistic regression, the dependent variable is a discrete variable representing a choice from either binary (0/1) or polytomous score categories (i.e., 1, 2, . . . k). In the binary logistic regression situation, the dependent variable is assumed to have a binomial distribution. This is the probability distribution of the number of successes in a sequence of n independent success/failure experiments, often called Bernoulli trials (Ross, 1994). Flipping a coin multiple times is a good example of a Bernoulli trial which has two possible outcomes: a head (0) and a tail (1).

In the polytomous logistic regression situation, the dependent variable has more than two response categories and is assumed to have a multinomial distribution. In this, each experiment results in exactly one of the fixed finite number k of possible outcomes, with probabilities $P_1, P_2, \dots, P_k$ (Ross, 1994). Tossing a dice a given number of times is a good example of a multinomial experiment which has six possible outcomes (i.e., 1, 2, 3, 4, 5, and 6). A binomial experiment can be seen as a special case of a multinomial experiment where each trial of the experiment can have only two possible outcomes.

One thing to note in logistic regression is that what is being predicted in simple logistic regression is the probability of the dependent variable (Y_i) being a certain outcome category (k), given the value of the independent variable (X_i), not the actual value (Y_i) of the dependent variable itself. Such a conditional probability is often denoted $P(Y_i = k|X_i)$. More precisely speaking, it is the *logit* (or log odds ratio) of the success probability for the dependent variable that is being predicted in binary logistic regression. In the case of the multi-category logistic regression, it will be a set of logits of the success (or failure) probabilities for dichotomized responses for the dependent variable. Then the success probability or score category probabilities are usually obtained from the estimated parameters and logit values obtained from the regression model.

Assumptions

In logistic regression, the dependent variable is categorical and assumed to have a binomial or multinomial distribution. Logistic regression assumes a linear relationship between the independent variables and the log odds (logit) of the dependent, although it does not require linear relationships between the dependent and independent variables. In addition, lack of multicollinearity is assumed among the independent variables, given the linear relationship between the independent variables and the logit for the dependent variable.

Logistic Regression for a Dichotomous Dependent Variable

In logistic regression, the base model is used to predict the success probability. One disadvantage of the probability prediction model, when viewed from the GLM framework, is that it does not have a mathematical form equivalent to linear regression. For this reason, the probability model is converted to a logit model so that it can have a mathematical form resembling linear regression.

First of all, in the probability model, what we are trying to predict is the probability of the dependent variable being 1, given the value of an independent variable or given the values of independent variables. Such a probability is often denoted $P(Y_i = 1|x_i)$ in simple regression, and $P(Y_i = 1|x_{1i}, x_{2i}, \dots, x_{mi})$ in multiple regression. When the binomial distribution is used to model a binary dependent variable, the success probability given the values for a set of independent variables $(x_{1i}, x_{2i}, \dots, x_{mi})$ can be expressed in the following manner:

$$P(Y_i = 1|x_{1i}, x_{2i}, \dots, x_{mi}) = \frac{e^{\beta_0 + \beta_1 x_{1i} + \beta_2 x_{2i} + \dots + \beta_m x_{mi}}}{1 + e^{\beta_0 + \beta_1 x_{1i} + \beta_2 x_{2i} + \dots + \beta_m x_{mi}}} \quad (3)$$

Here, e is the base of the natural logarithms (2.71828182846). The relation between the success probability $P(Y_i = 1|x_{1i}, x_{2i}, \dots, x_{mi})$ and a continuous independent variable can be nonlinear. The nonlinear relationship between the variables can usually be depicted in the form of an S-shaped curve. Nevertheless, the right side of the equation does not have a mathematical form equivalent to a linear regression. Thus, the probability model is converted in two steps: (a) conversion first to an odds model and then (b) conversion to a log odds (logit) model. One thing to note is that there is no error term in logistic regression. In logistic regression, we deal with probabilities. Probabilities themselves are methods of taking care of randomness and inaccuracy of prediction.

In the first step, the equation for the success probability is manipulated in such a way that we have the odds $[P/1 - P]$ rather than the success probability on the left side of the equation, as shown below:

$$\frac{P(Y_i = 1|x_{1i}, x_{2i}, \dots, x_{mi})}{1 - P(Y_i = 1|x_{1i}, x_{2i}, \dots, x_{mi})} = e^{\beta_0 + \beta_1 x_{1i} + \beta_2 x_{2i} + \dots + \beta_m x_{mi}} \quad (4)$$

The second step of this conversion involves transforming the equation further to a log odds (or logit) model. To go from the odds to the logit model, we should add the natural log to both sides of the equation. When this two-step conversion is completed, the right side of the equation for logistic regression finally takes a mathematical form similar to linear regression, as follows:

$$\ln\left(\frac{P(Y_i = 1|x_{1i}, x_{2i}, \dots, x_{mi})}{1 - P(Y_i = 1|x_{1i}, x_{2i}, \dots, x_{mi})}\right) = \beta_0 + \beta_1 x_{1i} + \beta_2 x_{2i} + \dots + \beta_m x_{mi} \quad (5)$$

The log odds or logit $[\ln(P/1 - P)]$ have many of the useful properties of an ordinary linear regression (Hosmer & Lemeshow, 1989). The logit is assumed to be linearly related to the independent variables. It is continuous and can change from negative infinity to positive infinity.

$$\text{Logit}[P(Y_i = 1|x_{1i}, x_{2i}, \dots, x_{mi})] = \beta_0 + \beta_1 x_{1i} + \beta_2 x_{2i} + \dots + \beta_m x_{mi} \quad (6)$$

In binomial logistic regression, the slope parameter associated with β_1 tells us about how much change there would be in the logit for a dependent variable when there is a one-unit

change in the independent variable X_i , given the fixed values of other independent variables. The Wald tests for the significance of the parameters are available to test whether the intercept and slope parameter are significantly different from zero. In logistic regression, the odds ratio for the compact and augmented models is often used as a measure of effect size. There are also R^2 -like (pseudo- R^2) indices that can be used as a measure of effect size for a newly added variable in multiple regression.

There are two major types of R^2 -like values used in logistic regression: (a) unadjusted and (b) adjusted values (max-rescaled). The unadjusted R^2 refers to the so-called Cox and Snell's (1989) index, whereas the adjusted one is Nagelkerke's (1991) index. One problem of unadjusted R^2 values is that the maximum can be less than 1.0. In contrast, adjusted R^2 values, which are more widely used, are obtained by dividing the unadjusted R^2 by its maximum value so that it varies from 0 to 1. At the moment, however, no absolute standards for interpreting the sizes of these values exist, except the recommendation that they can be compared across models on the same data in a relative way.

Logistic Regression for a Polytomous, Dependent Variable

Logistic regression for a binary dependent variable can be directly extended to a dependent variable with more than two outcome categories (Agresti, 2002; French & Miller, 1996; Zumbo, 1999). Logistic regression for a polytomous, ordinal dependent variable usually involves splitting the dependent variable with k response categories into $k - 1$ dichotomized response categories (or variables) and then applying binary logistic regression to these dichotomized responses simultaneously.

There are three different kinds of dichotomization schemes used in logistic regression for an ordinal variable: (a) cumulative logits, (b) adjacent categories logits, and (c) continuation ratio logits (Agresti, 2007). The *cumulative* logit scheme estimates the probability that the dependent variable falls at or below a particular score point (k) relative to the probability that the variable falls above k . On the other hand, the *adjacent categories* logit scheme estimates the logit for the probability that a higher category relative to the adjacent lower one is modeled; it is precisely this paired comparison that recognizes the ordering of the categories. In the *cumulative continuation ratio* logit scheme, each score category is contrasted with a grouping of score categories from a lower (or higher) level of the ordinal response scale.

Table 1 illustrates these three dichotomization schemes in each of the three logit models for a hypothetical, ordinal dependent variable. When the dependent variable has 5 response categories, there will be a total of 4 non-redundant, dichotomized responses possible for the dependent variable. The logit for each of the dichotomized responses can be formed. This also means that the parameters associated with each independent variable should be estimated along with the intercept parameter.

Table 1 Three dichotomization schemes for polytomous logistic regression

Dichotomization schemes	Dichotomized responses			
	1	2	3	4
Cumulative	1 vs. 2, 3, 4, 5	1, 2, vs. 3, 4, 5	1, 2, 3 vs. 4, 5	1, 2, 3, 4 vs. 5
Adjacent categories	2 vs. 1	3 vs. 2	4 vs. 3	5 vs. 4
Continuation ratio	A 1 vs. 2	1, 2 vs. 3	1, 2, 3 vs. 4	1, 2, 3, 4, vs. 5
	B 1 vs. 2, 3, 5	2 vs. 3, 4, 5	3 vs. 4, 5	4 vs. 5

8 MULTIPLE REGRESSION

One particular kind of dichotomization scheme that is most frequently used is a cumulative logit scheme called a proportional odds ratio model (McCullagh, 1980). In the cumulative logit model, the proportional log odds (logit) for each dichotomized response can be expressed as:

$$\text{Logit}[P(Y_i \leq k | x_{1i}, x_{2i}, \dots, x_{mi})] = \beta_0 + \beta_1 x_{1i} + \beta_2 x_{2i} \dots + \beta_m x_{mi} \quad (7)$$

Equation 7 suggests that, when the dependent variable has five response categories ranging from 1 to 5, there could be a set of four related logit models possible for the dependent variable (shown in the equations below). One interesting feature of the models is that the slope parameter associated with a particular independent variable is assumed to be the same across all of the dichotomized responses, but the intercept parameter can be different for each dichotomized response. The estimation of these model parameters is done for all of the dichotomized logit models simultaneously.

$$\text{Logit}[P(Y_i \leq 1 | x_{1i}, x_{2i}, \dots, x_{mi})] = \beta_{01} + \beta_1 x_{1i} + \beta_2 x_{2i} \dots + \beta_m x_{mi}$$

$$\text{Logit}[P(Y_i \leq 2 | x_{1i}, x_{2i}, \dots, x_{mi})] = \beta_{02} + \beta_1 x_{1i} + \beta_2 x_{2i} \dots + \beta_m x_{mi}$$

$$\text{Logit}[P(Y_i \leq 3 | x_{1i}, x_{2i}, \dots, x_{mi})] = \beta_{03} + \beta_1 x_{1i} + \beta_2 x_{2i} \dots + \beta_m x_{mi}$$

$$\text{Logit}[P(Y_i \leq 4 | x_{1i}, x_{2i}, \dots, x_{mi})] = \beta_{04} + \beta_1 x_{1i} + \beta_2 x_{2i} \dots + \beta_m x_{mi}$$

Once the regression parameters are estimated, the probabilities for $Y_i \leq k$ for each dichotomized response can be computed from the estimated parameters and the logit values obtained for each of the logit models. Then these probabilities are used to compute the probabilities for each of the score categories (or the probability of the dependent variable being k), as follows:

$$P(Y_i = k) = P(Y_i \leq k) - P(Y_i \leq k - 1) \quad (8)$$

The estimated intercept and slope parameters and effect sizes in multinomial logistic regression can be interpreted in a way similar to those of the binomial logistic regression. One interesting difference is that the expected score for the dependent variable can be computed by aggregating the estimated probabilities for all of the dichotomized responses. One recent area of applied linguistics in which logistic regression is increasingly used is item bias studies in language testing, often called differential item functioning (DIF) studies (Lee, Breland, & Muraki, 2005; Ross & Okabe, 2006; Breland & Lee, 2007). Logistic regression is implemented in major statistical packages, such as SPSS (Logistic Regression), SAS (Proc Logistic), and R (GLM).

Poisson Regression Models

Poisson regression is a form of regression used to model frequency data and contingency tables. Poisson regression is appropriate when the dependent variable is count data that are assumed to have a Poisson distribution. In Poisson regression, the logarithm of the expected count (frequency) can be modeled as a linear function of the effects of categorical variables and their interactions. When the Poisson regression is applied to contingency tables of count data, it is sometimes called a *log linear* model. In such a case, it will be the logarithm of the expected cell frequencies in a contingency table that is modeled in the regression. The Poisson regression can also be seen as a GLM that uses the logarithm as

a link function.

In both Poisson and logistic regression, the dependent variable is transformed by using a log function in the exponential framework. One difference, however, is that it is the expected counts that are transformed through the log function for the dependent variable in Poisson regression, while it is the odds that are transformed in logistic regression. In a Poisson regression model, the natural logarithm of the count is modeled by a linear combination of the intercept parameter and the slope parameters associated with independent variables, as shown below:

$$\text{Log}(Y_i | x_{1i}, x_{2i}, \dots, x_{mi}) = \beta_0 + \beta_1 x_1 + \beta_2 x_2 \dots + \beta_m x_m \quad (9)$$

Poisson regression assumes that the mean equals the variance. If the variance is greater than the mean, the frequency data are said to be *over-dispersed*. Over-dispersed data have standard errors and *p*-values that are too small. Some statistical software (such as SAS) has an adjustment called the Pearson adjustment that corrects the standard errors and gives more accurate *p*-values. As in logistic regression, the tests of statistical significance for the estimated intercept and slope parameters are available, as well as pseudo- R^2 effect size values, in Poisson regression. Poisson regression can be implemented in major statistical packages, such as SPSS (GENLIN), SAS (GENMOD), R (GLM), Stata (Poisson), and Microsoft Excel (Xpost).

Myths About Second Language Vocabulary Learning

KEITH S. FOLSE

In gaining proficiency in any second language (L2), learners have to grapple with new pronunciation, syntax, pragmatics, spelling, composition, and vocabulary. Though many language courses or programs still tend to focus on grammar (Folse, 2004), for our English-language learners (ELLs), the most important of these areas is arguably vocabulary. Learners can, for example, get by with weak or even incorrect syntax, but a lexical gap can immediately bring any conversation to a complete halt.

Prior to 1990, relatively little L2 research on second language vocabulary learning existed. In the early 1990s, L2 studies tended to reflect that period's affinity for works on learner strategies, as evidenced by Sanaoui's excellent 1995 study of adult students' vocabulary learning strategies. From this initial research on strategies, lexical research quickly burgeoned to other aspects of vocabulary learning and teaching, with hundreds of quantitative and qualitative works in various categories, including methods of vocabulary instruction, the effect of different practice activities, and the words learners need. Laufer, widely recognized as a leading pioneer in research into classroom vocabulary teaching and learning techniques, compiled a detailed time line of influential L2 vocabulary studies, demonstrating how L2 lexical research has progressed (Laufer, 2009).

Vocabulary Myths

In *Vocabulary Myths* (2004), I wrote about eight myths that were pervasive in our field—three of which are still widely accepted as fact despite clear empirical evidence to the contrary. The eight myths debunked in *Vocabulary Myths* are: (myth 1) grammar is more important than vocabulary in learning a foreign language; (myth 2) word lists are ineffective in learning vocabulary; (myth 3) vocabulary should be presented in semantic sets; (myth 4) the use of translations is a poor way to learn new vocabulary; (myth 5) guessing words from context is a useful way to learn a lot of vocabulary quickly; (myth 6) the best vocabulary learners make use of one or two really good specific vocabulary learning strategies; (myth 7) a monolingual dictionary is better than a bilingual one for learning new vocabulary; (myth 8) vocabulary is covered enough in our curricula and courses.

The research debunking these myths is clear: all eight of these myths are indeed myths. The good news for our learners is that since 2004 our field has evolved to the point that five of these myths are no longer as pervasive among teachers as before. A perusal of any L2 journal or TESOL conference program will now reveal significantly more attention to vocabulary, so it is fair to say that most educators now recognize that vocabulary is indeed extremely important (myth 1). Likewise, there is certainly a strong and growing increase in the amount of attention that vocabulary receives in our curricula and courses (myth 8), though many ESL (English as a second language) programs for adults still do not include a systematic vocabulary component (Folse, 2010). As a textbook author who works with several different publishers, I know that vocabulary lists in textbooks have made a comeback, so teachers no longer automatically shun vocabulary lists (myth 2). As we move

away from the once indefatigable role of comprehensible input to a return to emphasis on explicit teaching, our field seems to have abandoned interest and therefore research on learning strategies (myth 6). In fact, more is written now on the teaching of vocabulary than on learner strategies (Folse, 2009). Finally, the dictionary debate (myth 7) seems to have transitioned from monolingual versus bilingual to traditional versus corpus-informed learner dictionaries (Folse, 2011) as more research and student-learning materials are produced from huge computer-driven corpora.

If we believe these five myths are espoused by fewer professionals today, we end up with three remaining myths revolving around teaching words in semantic sets (myth 3), using translations to learn new vocabulary (myth 4), and promoting the use of context clues as a good method to learn new vocabulary (myth 5).

Myth 3: Vocabulary Should Be Presented in Semantic Sets

There are two common ways to introduce vocabulary: in semantic sets or in thematic units. A coursebook using semantic sets would have three distinct lessons on days of the week, clothing, and sports, and each lesson would include a semantic set, or list, of those items. In a thematic coursebook, these same words would be distributed across all of the lessons in the whole book. In this course, one lesson called “Luke’s Saturday Game” might include a dialogue or passage about a person who bought some *sneakers* to play *basketball* in a very important game last *Saturday*, thus including an item—but not all—of clothing, sports, and days of the week.

Learners have more difficulty learning new words presented in semantic clusters than they do learning semantically unrelated words. Waring (1997) found that Japanese learners needed about 50% more time to learn related word pairs than unrelated pairs. Similarly, Tinkham (1997) concluded that semantic grouping actually has a negative effect on vocabulary learning while thematic clustering facilitates learning.

Research has consistently shown that the use of semantic sets can confuse learners and hinder vocabulary retention, but organization by semantic sets continues because it is easier to present vocabulary in semantic sets than design creative passages that include all of the words in a vocabulary list. The bottom line, though, is that learners remember vocabulary more easily when the vocabulary is presented in thematic sets such “Luke’s Saturday Game.” Using thematic sets may also be superior because the items first presented are higher frequency than other semantic set members (e.g., Saturday and Sunday are more frequent than Wednesday and Thursday) and because they are presented in frequent collocations such as *Saturday and Sunday* or *Saturday night*. Therefore, learners’ attention is focused not only on the target words but also on collocations that increase learners’ formulaic language.

Myth 4: The Use of Translations Is a Poor Way to Learn New Vocabulary

Without a doubt, teachers need to encourage the use of the target language in the classroom for all the obvious reasons. However, when learners first encounter a new word, it is normal for learners to translate the word in their head or in their notebooks.

The myth that translations are not useful assumes that establishing a mental link with the first language (L1) translation is somehow harmful or does not actually happen in the real world. When given a choice, learners prefer translations; in addition, translations have proven more effective than English glosses in vocabulary learning (Hulstijn, 1992; Knight, 1994; Prince, 1995; Laufer & Shmueli, 1997; Grace, 1998).

Noted vocabulary expert Paul Nation (1982) concludes that learning of vocabulary is faster for many learners if the meaning of the word is given through an L1 translation first, a conclusion reached in many prominent vocabulary studies. For example, Hulstijn,

Hollander, and Greidanus (1996) found that translations of the French vocabulary provided as glosses in the margin resulted in better vocabulary learning. Further empirical proof comes from a study of Dutch university students of Italian (Lotto & de Groot, 1998), where word retention scores were significantly higher for the students working with translations than for those who had pictures. In addition, Grace (1998) noted that translation is a viable if not preferable option for many English learners of French at the beginning level. Her results showed that students who had access to a glossary in L1 were more successful at retaining new vocabulary, probably because they had the opportunity to confirm the correct meanings. Laufer and Shmueli (1997) discovered that words glossed in L1 were always retained better than words glossed in English. Finally, Prince (1995) compared words presented in context with words presented with a translation and found that less proficient students were able to recall more items when they had learned the words in the translation condition rather than in the context condition.

In sum, translations are not bad; they can in fact be a helpful tool in learning new foreign-language vocabulary. As a result, future research should move to more pertinent questions such as whether translations work better with certain kinds of vocabulary (e.g., verbs or idioms) or whether translations might work better at the initial presentation stage or subsequent review stages.

Myth 5: Guessing Words from Context Is a Useful Way to Learn a Lot of Vocabulary Quickly

Guessing the meaning of unknown vocabulary from context is certainly a good reading strategy to compensate for not knowing a word, but it is not an efficient or practical way to overcome the huge lexical deficit that our ELLs face. The myth that guessing from context is a good way to learn vocabulary is based on the false assumption that learning a second language is a very similar process to learning our first language. In our L1, we did not explicitly learn most of our vocabulary; we acquired our vocabulary through seeing and hearing the words numerous times in many contexts.

In contrast, an L2 learner does not have the luxury of encountering a word numerous times. Most adult learners have a very short time to achieve a certain degree of fluency in the second language. They do not have the time needed for the extensive reading necessary to meet academic vocabulary multiple times in natural language. Our students are *learning* a second language and are under very different constraints than when they *acquired* their first language through comprehensible input over 18+ years. Cobb (1999, p. 345) aptly sums up this dilemma with, "Students typically need to know words measured in thousands, not hundreds, but receive language instruction measured in months, not years."

In the heyday of communicative language teaching with its emphasis on communication and "natural approach" techniques, instruction of grammar, spelling, and vocabulary as well as teacher actions such as explicit error correction were greatly frowned upon. Vocabulary was not taught; it was assumed that students would automatically acquire whatever material—including vocabulary—was made available by the comprehensible input. Learners (and teachers in training) were encouraged not to focus on unknown words but rather to focus on understanding the gist.

Ironically, a learner must have a large vocabulary to be able to guess the meaning of unknown words from surrounding context clues successfully. This lexical limitation puts lower-proficiency students or students with less vocabulary at a distinct disadvantage. In research on the effect of type of written practice exercise (Folse, 2006), I found that learners who know more words are able to use those known words to learn even more words from context; thus, limited lexical knowledge adversely affects a learner's ability to correctly guess a word's meaning from context, let alone actually learn that word. (Successful guessing does not guarantee successful learning.)

How different is this scenario for native and non-native speakers? In a passage, a native speaker may find only one unknown word, so all of the other words provide the native speaker with a huge context of known words. In sharp contrast, the L2 learner with the same reading passage most likely faces *multiple* unknown words that serve as non-clues or misleading clues. In spite of their lexical knowledge, native English speakers are not very successful at guessing word meanings from real contexts because helpful context clues are surprisingly rare in real language excerpts (Schatz & Baldwin, 1986). Therefore, it is unclear why we expect L2 learners, who lack the depth and breadth of lexical knowledge possessed by native speakers, to be successful at this when native speakers are in fact not so successful.

Hulstijn (1992) found that using natural context to guess word meanings is a very complex and error-prone process for L2 learners. In his study, learners were more likely to remember the form and meaning of a word when they inferred its meaning by themselves than when the meaning has been given to them; however, these same learners were more likely to infer an *incorrect* meaning of an unknown L2 word in an L2 text when no cue has been given to its meaning. In other words, left on their own, L2 learners are not good guessers when dealing with real texts (as opposed to their language textbooks which have been written specifically for their proficiency level in the L2).

In a study of adult intermediate ESL university students, Wesche and Paribakht (1994) compared a reading-only group with a reading-plus-treatment (i.e. with follow-up written practice exercises) group. While the reading-only group did have gains in word knowledge, the gains were significantly larger in the reading-plus-treatment group and exhibited a greater depth of knowledge of the target words. What ESL students need is not just exposure to reading materials; they need reading with explicit, planned vocabulary work.

Everyone can attempt to guess the meaning of unknown words from context, but L2 learners are ill equipped to do so. Lexical learning from context clues can take place, but explicit instruction has been shown to be more efficient for L2 learners whose goal is to learn a large number of lexical items quickly.

Multimedia Digital Engagements by Readers and Learners

ROBERT J. TIERNEY

Various researchers, theorists, and applied scholars are reinvigorating, expanding, and shifting our view of reading comprehension as they explore the nature of the meaning making within digital environments. These scholars include: social anthropologists interested in digital literacies as literacy practices and events; cultural and critical theorists intent on studying the politics of individuals and group identities; linguists including socio-semioticians interested in the advent of language systems especially the shifts in signs via new media; cognitive psychologists interested in learning in the context of the new knowledge economies and literary theorists intrigued by discussions of author–reader–text relationships provoked by new forms of text and educators interested in the nature and role of learning.

Their interests and their pursuits stem from: shifts in the ever increasing magnitude of information, how it is generated, shared and enlisted; how ideas spread and mutate globally and locally; the changing nature of modes for the representation of ideas and exchanges especially with the integration of text, image, and sound in multilayered and dynamic fashion via networks; shifts in the observed social practices at the hands of the advent of new digital tools; the momentum and ubiquitous nature of digital engagements in all aspects of our lives especially with the advent of global access via cellular, wireless, and broadband possibilities.

Changing Nature of Information Access and Knowledge Demands

Julie Coiro, Michele Knobel, Colin Lankshear, and Donald J. Leu (2008, pp. 2–3) have suggested that digital literacies have been

adopted by so many, in so many different places, in such a short period, and with such profound consequences. No previous technology for literacy permits the immediate dissemination of even newer technologies of literacy to every person on the Internet . . . [or provides] access to so much information that is so useful, to so many people.

The Berkeley School of Information and Management Systems (Lyman & Varian, 2003) suggest that information exchange is growing across all mediums and that overall the rate is approximately 30% per year. They estimated in 2002, that approximately 800 megabytes were being produced on average per person per year or the equivalent of 30 feet of books. Their data indicate that the amount of print is not diminishing, but magazines, periodicals and, in terms of sheer amount, office documents seem to be displacing books. Telephone exchanges aside, the dominant method of exchange has become digital (Internet, instant messaging, etc.). And, at the same time, as the migration of information seems less restrained by national borders or international agreements as global networks emerge and shift with global interests and demand, as wikis, blogs, and the Internet offer open invitations to all

of us to author submissions, exercise forms of authority, artistic expression, or contribute news or views.

These developments are significant for reading comprehension as they shape the knowledge demands and developments globally and locally for individuals and groups. They represent different forms of exchange and new forms of representation, which may involve concomitant shifts in how comprehension proceeds. Indeed, questions have arisen as to the impact on meaning making, especially upon the nature of the engagements including processes and outcomes. Some early studies, which focused on the use of the Web, confirmed what many feared—namely, many individuals lacked the skills to successfully access and assess knowledge that might be available on the Web. For example, Eagleton (2005) found middle school students without experience with Internet inquiry often made “hasty, random choices with little thought and evaluation” (p. 3). She coined the approach as a form of “snatch and grab.” However, more recent studies suggest that students may vary significantly as they become more Web-savvy with experience. For example, in a study in selected urban and regional schools in Australia (Singh, Mallan, & Giardina, 2008), it was found that most students were enlisting the Web as the primary source for information and were using a range of strategies to both access and assess that knowledge. When accessing the Web, approaches often involved visits to multiple sites, including sites deemed as likely to be more credible. At times forms of knowledge aggregation and averaging were enlisted to verify the factual nature of ideas as well as the use of Google and Wikipedia as the first “port of call” or as a backup to searches.

Meaning Making With Changing Nature of Modes for the Representation of Ideas and Exchanges

With the proliferation of Web sites or multilayered, multimodal, and multi-nodal hubs, a number of scholars have been engaged in a consideration of the nature of reading comprehension processes and outcomes that are propelled by the multilayered intertextuality afforded across layers of text and images. On the positive side, it has been suggested that this layering and linkages may expedite both the multiplier effects of meaning making across a library of images, words, and sounds interwoven in ways that call for the integration of multiple sources and making of intertextual connections across textual spaces including the multimedia elements that are mixed together in ways that create complex compounds of meanings and active agents for transmediation, or what Forman (1998) has described as “the type of constructive conflict we deem to be the power of this multisymbolic approach to education” (p. 187). In both digital and non-digital environments Spiro (2006a, 2006b) and his colleagues (Spiro, Collins, Thota, & Feltovich, 2003) have suggested and shown that such multilayering can facilitate more complex learning. They have demonstrated the power of crisscrossing multilayered renditions of ideas in the education of medical practitioners and teachers in ways that afford understandings that are more generative and flexible especially when they are fashioned as case-based knowledge.

On the negative side, as researchers have predicted and found such meaning making is not always trouble-free as one moves from one site to another and across layers. Indeed, with hypertext, depending upon the experiences of the meaning makers, learning may be constrained by a kind of labyrinth (Snyder, 1996) and movement proceeding from one text to the next and one link to the next might be constrained and be overly text-centric—meaning makers may become lost, at a dead end, or miss what they perceive to be a key item. Sometimes, the ambitions of the author of this multilayered text may not match the learner’s interests, background, sophistication, and prowess (Burbules & Callister, 1996). At times, the meaning making within the labyrinth of some hypertexts may be overly

text-driven as a result of the forms in which ideas are represented or the meaning makers' comprehension strategies or agility. In conjunction with their exploration of overly text-driven responses to hypertext novels, Teresa Dobson and Rebecca Luce-Kapler (2005) suggest there may be a need to prompt more consciousness by the reader of his or her approach to enrich the meaning makers' engagement in hypermedia.

How meaning makers position themselves (including purpose setting, navigating sites, rapidly discerning relevance, and integrating ideas) has been the subject of a number of studies of online meaning making. For example, Alexander, Jetton, Kulikowich, and Woehler (1994), based upon their observations of comprehension on the Internet, suggest that the multilayered nature of these digital environments can demand of meaning makers a high degree of self-regulated navigation, an ability to retain and revisit focus, as well as skill weaving together or managing multiple inputs. More recently, Coiro and Dobler (2007), examining the online comprehension strategies of successful sixth grade learners given an assignment with a preset Internet site (i.e., on tigers) found that one of the key distinctions of successful online comprehension is tied to the more frequent use of forward inferencing (versus backward inferencing) which is aroused at the point of a hypertext link. They suggested

internet reading seems to demand more attempts to infer, predict and evaluate reading choices . . . to require readers to orient themselves in a new and dynamic three-dimensional space . . . to figure out how to get back to where they were.

They suggested that the self-regulation of online comprehension seems tied to a similar set of recursive strategies (planning, aligning, drafting, revising) of past models of composing (e.g., Tierney & Pearson, 1983). Coiro and Dobler (2007) posit that online comprehension involves planning within and across Web sites, predicting and following leads, monitoring how and where to proceed, and evaluating relevance and judging merits. They noted that there are physical dimensions associated with these activities (e.g., scrolling, clicking) and speculated that the online environment might be more demanding and complex than offline. The online demands of meaning making appear to require more use of forward inferencing or predicting as meaning makers attempt to navigate the layers of text or information—to search, select, and integrate across sources. Forward inferencing seems to arise in conjunction with an interest in determining where links might lead and in assessing the possible saliency of what may be uncovered. When using search engines they found that users often relied on annotations offered with hyperlinks yielded from the search as a means of assessing the degree of relevance or the likelihood that an identified site would yield more or less relevant results. Coiro and Dobler (2007) stressed that knowledge of informational Web site structures as well as skill in using search engines appeared to influence both the navigation and weaving together toward the integration of ideas. Their characterization parallels Spiro's (Spiro, et al., 2003; Spiro, 2006a, 2006b) observations of the kind of crisscrossing of the terrain ideas that learners might navigate as they are engaged in complex knowledge acquisition akin to Stephen's (1998) notion of quick cutting across dense images.

The importance of forward inferencing predates research of online reading comprehension. The importance of planning, predicting, and composing has been highlighted in previous notions of reading comprehension including schema-based views of reading as articulated in the progressive refinement model of comprehension offered by Collins, Brown, and Larkin (1980). It is also consistent with the findings from formative studies of teaching reading comprehension. For example, forward inferencing and predicting emerged as the cornerstone for improving reading comprehension in studies under the direction of Russell Stauffer (1969) of the Directed Reading Thinking Approach and studies on structured

overviews and other learning adjuncts for content area reading studied and advocated by Herber (1970) as well as Manzo's work on reciprocal questioning (Manzo, 1969). Likewise studies of reading and writing across multiple texts afforded similar insights. For example, McGinley (1992), who researched college students using multiple sources to develop essays, observed that the more successful students were more focused (versus haphazard) and in turn this focus helped guide the shifts, search of, selection, and use of different sources. McGinley (1992) stressed that successful meaning making involved a kind of internal collaboration or dialectic as the meaning maker pursued agency as "a reader of the source articles, an essay writer, an essay reader, a note writer, and a note reader" (p. 241) and a reader of themselves.

Developmental Considerations: Matters of Agency and Identity

How readers position themselves emerges as key to how successful readers proceed across a range of situations. Dyson (1995) has suggested that children's major developmental challenge is not simply to create a unified text world but to move among multiple worlds and coordinate multiple space/time structures toward defining the self, including how one is placed in the company of others. As Dyson (1995) stated: "Children are not first and foremost learners; they are first and foremost people living the complexities of their day-to-day lives" (p. 36). Children seek to "imagine" relationships and situate themselves socioculturally and ideologically. With older learners in the field of sociology, Mathison (1996) surmised that success as a sociologist (insofar as critiques revealed) comes with exploring identity in a fashion that involves engagements with fellow sociologists.

Not surprisingly with the advent of the Internet and social networking as well as rich socially oriented descriptions of non-digital meaning making, agency and positionality have emerged as important elements in reading comprehension. Rather consistently, the agency of the meaning maker (especially how the meaning maker positions himself or herself or approaches or navigates the text[s] or digital space) is being seen as key to their engagement with the ideas that were explored, the strategies that were employed, as well as how the meaning maker wishes to position himself or herself in the company of others.

These multiple engagements befit the view of meaning makers as a kind of multivocal and multi-perspectival pursuer of understandings akin to what was suggested by Barthes, or other views of the social construction of multiple meanings. That is, the meaning maker is engaged in constructing selves or multiple personas in the company of others or a form of embodiment—a secondary engagement with or participation in the worlds constructed across, or within, or by layers of text and other media. At the same time, a meaning maker adopts one or more personae that are then positioned with others and their worlds in a fashion growing out of their subjectivities, alliances, choices, etc. In various digital spaces, the multiple embodiments of the meaning makers has been observed across a variety of literacy events as integral to participation as well as successful meaning making or engagement in the media. For example, Rogers and Winters (2006), Alvermann, Hagood, and Williams (2001), and Hull and Nelson (2006) have argued that students are afforded the possibility of having their literacy practices travel across spaces, in and out of schools, blurring traditional boundaries and forms of literate practices. These spaces also allow students to "juxtapose and transform genre practices for critical purposes, engage in the playful instability of genres, selves, and messages, and re-narrate their stories and identities in the process" (Rogers & Winters, 2006, p. 29).

Similarly, in the research on hypertext and gaming, Squire (2006) and Gee (2003) suggest knowing may go beyond moving from print to image to virtual or real environments interfaced with tools which simulate opportunities to perform in situations and try on identities

as one experiences and enters such worlds. As meaning makers interact with one another around games and music and other exchanges, Sefton-Green (2006) and Rampton (2006) have observed youth in pursuit of similar agency. In particular, they have found that youth use the “snatches” of music, phrases, and so on to rework, remix, adapt as they position themselves based upon interactions with others and in so doing assert their agency and explore possible identities for themselves.

Observations of students engaged in the use of instant messaging suggest that the digital medium supports a fluid form of identity construction. In particular, Lewis and Fabos (2005) found that when adolescents instant message with one another they can shift identity almost simultaneously as they interact with one another in the context of others. As Lewis and Fabos (2005) stated, “they enact identities that depend upon a running analysis of the on-line and off-line contexts” (p. 494). They describe adolescents who shift their interactions to fit their relationship and stance with respect to one another as they instant message each other in the company of groups (e.g., taking the role of confidant[e] or advisor or cynic or empathetic supporter with the different participants) and they do so in a fashion which is consistent with her or his overall sense of identity and understanding of the dynamics of the relationships.

Collective Meaning Making: Shifts in the Observed Social Practices at the Hands of the Advent of New Digital Tools

Notions of one’s identity and position exist within a social fabric of others at the same time as they contribute to a form of group meaning making. As such, meaning making is transferred from individualistic or reader-generated notions to notions of a wider collective. Indeed, building upon the work of Dyson (1995), Jenkins and his colleagues (Jenkins, Clinton, Purushotma, Robison, & Weigel, 2008) have introduced the notion of participatory culture prompted in part to befit the advent of social meaning making emerging across digital environments. As Jenkins et al. (2008) emphasize, “participatory culture shifts the focus of literacy from one of individual expression to community involvement. The new literacies almost all involve social skills developed through collaboration and networking.” Regardless of the mode, meaning making involves an interaction with oneself or groups in the context of how one networks with others, or the platforms with which one is composing or communicating, or both. The pursuit of expression, information exchange, or other forms of communication entail compositions from or for a widening network which the meaning maker(s) may have just expanded by entering the network and expanded further by linking with others. One would hypothesize that the nature of the meaning making may vary depending upon how the individual or group position themselves in relationship to such spaces which are likely to be changing over time in terms of who is interacting with whom, how, why, when, and where. Indeed, the complex nature of these spaces and how individuals and groups are located and displaced by them is apparent in studies of how historically marginalized groups form or find community or not via blogs, chatrooms, listservs, or a combination of online or offline spaces. For example, studies of the sense of community achieved for lesbians via e-mail listservs, blogs, and other spaces, also may dislodge or serve to marginalize individuals depending upon their performance as members of these groups and the norms that are applied or develop across time (e.g., Bryson, MacIntosh, Jordan, & Lin, 2006). Bryson et al. (2006) challenge the simple-minded almost utopian view that these digital environments serve as the foundation for a range of diverse spaces for all. As they suggest one might find a haven or prison or have a sense of belonging or dislodgement in such spaces.

Closing Comments

Comprehension exists amidst a world of ideas and people whether they are online, face to face, or engaged in transactions through written text. As meaning makers navigate the world of ideas there appear to be certain core meaning-making processes regardless of the environment (e.g., goal setting, questioning, refinement of meaning, predicting, and connecting ideas), at the same time as there is the view that there may be some differences that arise in conjunction with working within these new digital environments. Consider the search function within an online digital environment. With access to the Internet together with their own files, a meaning maker can quickly do a search of a range of documents and compile a listing of all references to a certain topic. In essence, a person can compile a stack of materials, which that person can examine historically or in a host of different ways. If the reader chooses to venture more widely and use a search engine (Yahoo! or Google, etc.), that person will likely generate large numbers of connections depending upon how they define the searches. And, these connections (or worlds of other texts and images that link and may inform one's meaning making) are at one's fingertips. The nature of these connections shifts with the searches that are employed, the libraries that are accessed or the questions and strategies used, or both, including the forward inferencing and organizing/compiling that may be enlisted. Again, the multilayered nature of such meaning making needs to be stressed. Ideas are linked into complex patterns that may range from stacks of texts and images sectioned off and posted within Web templates with links, or linear or temporally sequenced, or in a host of other patterns that may be varied during compilation and use or search and presentation. Just as form and function have an interplay in any architected space, so does the form, patterning, or management of ideas (in digital and traditional print) have an impact on the meaning making that occurs. When one designs a text from multiple sources—when one links or traverses multiple layers—one creates meanings that may be patterned or formed or architected in different ways. Meaning makers may be more or less successful with online engagements with ideas. They may vary in the degree to which they explore and mix ideas, create and critique, savor, digest and use them whether as fuel for reflection, discovery, expression, or verification. Simultaneously, meaning makers are engaged in conversations with themselves in the company of others—imagined or real. And, at a more macrolevel, this success is tied to how meaning makers are networked and positioned with others in the context of exchanges locally and globally. It is likely that online meaning making may be different in terms of the participants, venues or spaces, as well as the interplay between local and global, image and text, layer upon layer, node upon node. One of the values of contemplating meaning making online may be the shift to a fuller inclusion or consideration of collective meaning making versus more traditional models of reading comprehension, which have focused upon the individual over the group.

Narrative Approaches to Second Language Acquisition

ANNE POMERANTZ

Theoretical Premises

Narrative approaches to second language acquisition (SLA) research begin from the premise that human beings are storytellers (Polkinghorn, 1988). People make sense of their lived experiences and even themselves by constructing, continually revising, and sharing narratives. Indeed, psychologists like Bruner (1987, 1990) have posited that narrative is a specific mode of thinking common to all human beings. It serves, at least in part, as a way to manage novel or troubling situations by configuring disparate, contradictory, or unexpected events into a coherent, logical whole. Moreover, storytelling allows narrators to take a certain evaluative stance relative to the events chronicled in the tale, thus functioning to express and perpetuate particular moral understandings (Ochs & Capps, 2001). It is both within stories and through the act of storytelling that distinctions between what is right and wrong, what is expected and unexpected are articulated, questioned, and reworked. Yet narratives, in both their telling and their form, do not exist in isolation. They are always told in response to and in anticipation of other stories. As Bakhtin (1986) argued, narratives are fundamentally dialogic in two senses. They are always addressed to someone and populated by the voices of others.

This emphasis on human beings as creators and interpreters of meaning sets narrative approaches to SLA off from other, more positivist research traditions within the field that see meaning as located in an objective or readily perceptible reality (Pavlenko & Lantolf, 2000). It is precisely this acknowledgment of narrative as a shared sense-making process that attracts some SLA researchers to its study and analysis. These researchers seek an emic or insider's account of the cognitive, social, and emotional dimensions of SLA, one that is not necessarily open to etic or outside observation. A focus on narrative allows for rigorous examination of learners' perspectives, stances, moral frameworks, and social positions or relationships as situated in particular sociocultural contexts.

Insider Accounts of SLA: Narrative as a Sense-Making Process

In keeping with this viewpoint, the majority of narrative research in SLA has focused on issues of representation and interpretation in learners' autobiographical stories. That is, it has attended to narratives as evidence of the learner's sense-making process, examining how the language-learning events within them are ordered, explained, and evaluated. As Casanave (2005) explains, "narrative connects and configures parts of human experience into meaningful larger chunks, weaving them together in a storylike way such that episodes are seen as related to each other in time" (p. 18). As these chains of experience are formed, narrators work to rationalize and justify emergent relationships. Narrative thus imposes cohesion among otherwise disparate events, resulting in a particular interpretation of what happened.

Studies of language learners' diaries, for example, have yielded important insights with regard to how people engaged in domestic language courses or short sojourns abroad understand and interpret their motivations, emotions, and activities. Such work has shed light on psychological and social dimensions of language learning that are often invisible. Moreover, it has offered detailed descriptions of why learners choose to pursue particular courses of action or language-learning strategies. In one of the earliest diary studies in the field of SLA, F. Schumann depicted the physical discomfort she felt during her stay in Morocco and how this negatively affected her desire to study Arabic (Schumann & Schumann, 1977). Likewise, Campbell's (1996) introspective account of how she, as an experienced second-language learner enrolled in a short-term immersion program, set out to befriend her teachers and become part of their social group, described not only the manner in which she pursued this goal, but why she felt it was essential to her linguistic development. Taken together, these studies exemplify many common threads across early diary studies in SLA, in that they offer a first-person account of a short-term, formal, language-learning experience, written in the diarist's native tongue. The experiences are recorded as they happen and then subjected to further reflection and analysis by the author. Key themes and patterns are identified, resulting in a detailed account of the factors the diarist highlights as central to the language-learning experience.

Reconceptualizing the Learner in SLA: Narrative as a Site for Identity Construction

In recent years, small-scale diary studies have given way to larger, more theoretically motivated studies of language-learner narratives. For example, in an effort to understand the relationship between the language learner and the language-learning context, Norton (2000) analyzed the diaries of five female learners. She found that both the women's desires to use English outside the classroom and their opportunities to interact with other speakers of the target language were shaped by the ways in which they positioned themselves and were positioned by others in particular social encounters. Whereas previous accounts of SLA had cast factors such as motivation and anxiety as stable traits residing within individual learners, Norton argued for more attention to how one's desire to learn and use a particular language changes over space and time and is tied to specific, and generally inequitable, relations of power. Drawing heavily on feminist, poststructuralist theories of identity to understand the women's stories, but not on narrative theory itself, Norton grounded her examination of the focal texts in the idea that learners' identities are multiple, dynamic, negotiated, and often, but not always, negotiable. That is, as learners participate in and reflect upon various activities, their sense of who they are, or subjectivity, undergoes continuous, though not unlimited, change. Thus for Norton, narrative, in the form of autobiographical texts, became an important resource for illuminating how learners conceptualized their various identities and how these identities related to both their motivations to learn and their opportunities to use the target language in specific situations. In recognizing the relationship between the "complex social history and multiple desires" of language learners (Norton, 2000, p. 10) and their patterns of language use, Norton paved the way for more focused examinations of the role of identity in SLA.

Although narrative theory did not figure prominently in Norton's analysis of her participants' stories, much subsequent work in this vein has begun from the premise that autobiographical narrative is both reflective and constitutive of identity. As Ricœur put it, "To answer the question 'Who?' . . . is to tell a story of a life" (1988, p. 246, as cited in Pavlenko & Blackledge, 2004, p. 19). Indeed, Bruner has argued that we eventually "become the autobiographical narratives by which we 'tell about' our lives" (1987, p. 15). Many

contemporary studies of identity within SLA, therefore, consider how people's understanding of who they are changes as they acquire and use new linguistic resources. Such work asks (a) how access to a new language shapes the ways in which people understand themselves narratively, and (b) how these narrative self-understandings shape the ways in which people come to use language.

Pavlenko and Lantolf (2000), for example, examined the memoirs of 10 bilingual writers, noting how the authors engaged in a process of "self-translation" as they moved through a series of stages that included the loss and subsequent (re)construction of their identities. According to Pavlenko and Lantolf, the focal narratives spoke of both material and subjective border crossings, as the writers moved not only from one physical space to another, but from one sense of being to a new, and in some cases radically different, set of possibilities for selfhood. The writers had no choice but to renegotiate their identities as they struggled to make sense of themselves and to be recognized as certain kinds of people in their new linguistic environments. Like Norton, Pavlenko and Lantolf called for an approach to SLA research that would extend to include more emphasis on identity and learners' participation in new linguistic communities, but with an eye toward what narrative theory could contribute to this endeavor.

Theorizing Narrative Within SLA: Multidisciplinary Insights

As narrative research within SLA has matured, researchers have increasingly turned to insights from a multidisciplinary array of narrative theorists to guide their work. For example, psychologists, anthropologists, philosophers, and literary critics have long argued that, although the human propensity to apprehend experience within and through narrative is universal, the organization and structure of specific narratives varies historically and cross-culturally. Autobiographical narratives too, they contend, are shaped by the discourses and ideologies circulating in particular contexts. That is, the stories people tell about their lives are not original creations; rather, they inform and are informed by more widely held notions about what specific constellations of events could mean. In an extension of her collaboration with Lantolf, Pavlenko (2002) examined the published autobiographies of language learners in the United States at the turn of the 20th century. She found that the focal stories were infused with widely circulating and largely unchallenged ideas about the intellectual/moral superiority of English and the importance of using English to construct and defend one's identity as an American. Her analysis of these texts traced how these ideas came into being and eventually eclipsed other competing perspectives. Likewise, it revealed the extent to which individuals from the late 1880s until World War I drew on particular language ideologies to make sense of and craft their own language-learning experiences and achievements. Consequently, Pavlenko concluded that people's language-learning trajectories are constrained, to a certain extent, by the identity options available to them in particular contexts.

Taking a more social-psychological perspective, Coryell, Clark, and Pomerantz (2010) explored how heritage learners of Spanish enrolled in an online language course on the USA–Mexico border made sense of their linguistic histories as both individuals and members of a bilingual community. Drawing on insights from symbolic convergence theory, the researchers considered the dual role that shared "cultural fantasy narratives" played in terms of how the learners came to represent and interpret their linguistic trajectories. In particular, they connected specific common subthemes in the participants' stories to their perceptions, actions, and responses as heritage learners of Spanish within their community. On the one hand, the authors argued that these common subthemes coalesced to form a master cultural fantasy narrative which the participants then drew on to understand their

individual experiences with Spanish. On the other, the authors maintained that, as the participants told their stories, they reproduced the cultural fantasy narrative, thus contributing to its vitality and perseverance. Thus, Coryell et al. provided an additional lens through which to consider the relationship between individual stories and larger, shared narratives.

Language learners, however, are not without agency in crafting their autobiographical stories. The act of storytelling itself is an intentional form of identity construction. Ochs and Capps (2001) note that narrators often take a particular stance relative to the events and characters in their stories, presenting themselves and the activities in which they engage in a certain light. "Everyday narratives of personal experience," they argue, "elaborately encode and perpetuate moral worldviews" (pp. 45–6). Thus, autobiographical stories are neither decontextualized nor disinterested. Narrators appropriate, resist, and at times even transform various ideologies in making sense of their language-learning histories and trajectories. For example, Menard-Warwick (2004) examined how particular ideologies of gender, education, and migration shaped and were shaped by the stories immigrant language learners to the USA told about learning English in and out of school. Through close examination of the focal learners' autobiographical stories, she identified and analyzed the ways in which these narrators represented and responded to the opportunities, challenges, and contradictions they faced in their day-to-day lives. Although the learners often positioned themselves as constrained by various ideologies and economic circumstances, she also observed moments of great creativity and resilience within these texts. Thus, Menard-Warwick highlighted the importance of considering how individual language-learning trajectories are grounded in and interact with the larger social, historical, and economic context, while simultaneously emphasizing their idiosyncrasies. Her work, like that of other SLA researchers interested in the relationship between identity and additional language learning, views autobiographical narrative as the place where learners reconcile and enact their multiple, and at times even competing, subjectivities, as they make sense of who they are as complex, socially situated, emergent bilinguals or multilinguals. It is this emphasis on learner narratives as both constitutive of identity and embedded within particular social, historical, and ideological contexts that distinguishes such work from earlier examinations of individual learner diaries in SLA research.

Although most narratively oriented work in SLA has focused on identifying themes within and across learners' stories, a nascent body of research looks specifically at the focal narratives themselves as texts. Echoing an earlier call for a more literary approach to the analysis of diary data (Bailey & Ochsner, 1983), Pavlenko (2001) argued that language learners' autobiographies constitute a particular genre and should be examined as such. In keeping with this perspective, Vitanova (2005) drew on Bakhtin's concepts of consciousness, voice, and answerability to understand the autobiographical stories of highly educated Eastern European immigrants to the United States. She looked closely at the ways in which the narrator's voice in the story interacted with the voices of the other characters to appropriate, resist, or transform the subordinate social locations to which they were often assigned in the unfolding tale. Likewise, Ros i Solé (2007) referenced the notion of positioning to examine the roles indexical pronouns, reported speech, sequential ordering, and plot development played in situating the narrator textually in stories about interactions with members of the target-language community. As SLA researchers continue to adopt narrative approaches, such fine-grained textual analyses hold considerable promise, particularly when they are combined with attention to the sociohistorical contexts in which the focal stories are embedded.

Exploring the Intersection of Identity and Language Learning: A Focus on Narrative

In an effort to understand how identity formation accords with linguistic development, SLA researchers have begun to meld detailed examinations of learners' autobiographical narratives with focused observations and assessments of particular linguistic performances and trajectories. Kinginger (2008) reported a case study of six US college students enrolled in a study-abroad program in France. Specifically, she drew on narratives told during the process of life-history interviews, anecdotes related in journal entries, and periodic quantitative measurements of linguistic competence (e.g., appropriate use of academic language, forms of address, colloquial expressions, and speech acts) to understand the relationship between the focal participants' interpretive accounts of their sojourns in France and their linguistic development. Kinginger found that, while the participants varied with respect to their overall linguistic gains, a focus on the specifics of their experiences could not fully account for these differences. She then argued, like Norton, that the participants' life histories, linguistic aspirations, and imagined identities played a strong role in shaping their learning trajectories. Moreover, she added that "in the contemporary globalized world of study abroad in which linguistic immersion is increasingly a matter of choice and even of struggle" (p. 108), learners often require support in articulating and achieving particular language-learning goals, as just being physically present in a particular linguistic community is not enough to foster bilingualism. Kinginger's mixed-method approach offers a fruitful avenue for future inquiry, as it links a qualitative understanding of learners' experiences in the form of narrative analysis with a quantitative assessment of their linguistic competencies. In so doing, Kinginger forms a bridge between interpretative and positivist research, thus highlighting the strengths of each. Such approaches promise a more robust understanding of the ways in which learners' multiple identities and changing linguistic capabilities inform and interact with one another in specific instances and over long periods of time.

Charting New Directions in Narrative Research: Current Tensions and Limitations

As narrative research gains credence within the field, SLA researchers must nevertheless remain mindful of "whose language learning stories are being told" and "whose stories are still not represented in the genre" (Pavlenko, 2001, p. 233). Indeed, Pavlenko's reference to genre raises the additional question of what themes, characters, events, story lines, rhetorical devices, and so forth must be included in a story for it to "count" as a language-learning autobiography. Moreover, as Ochs and Capps (2001) have cautioned, not all stories are deemed worthy of telling. For a story to be told, it must be relevant and of value to both the narrator and the actual (or even potential) audience. For SLA researchers interested in narrative, this has resulted in an emphasis on stories of monolingual individuals becoming bilinguals or multilinguals. This preference often serves to obscure the stories of multilinguals who acquire additional languages. Furthermore, it contributes to the dominance of discourses within the field that cast monolingualism as the normal state of affairs and multilingualism as deviant and not worthy of study. Thus, it is important for SLA researchers not only to consider a wide variety of learner stories, but to recognize which stories remain unacknowledged or silenced. Moreover, they must attend in their analyses to the nuances of both the macro-level sociohistorical context in which the focal stories are told and the micro-level interactional context of the specific telling.

Despite increasing acknowledgment of narrative research as a valid mode of inquiry in SLA studies, it is important to remember that it still remains largely marginal within the field. Early on, Bailey and Ochsner (1983) observed that this marginality stems, at least in part, from the fact that a focus on narrative data necessitates a shift in epistemology and a different set of analytic tools, akin to those found in literary studies. To this end, narrative theory now boasts a daunting array of discourse analytic approaches born out of different scholarly traditions. Yet, despite these advances in the field of narrative inquiry itself, Pavlenko and Lantolf (2000) contend that narrative, as a form of data in SLA, is still frequently scorned because of the preference in the natural and social sciences for third-person, empirical observations over first-person accounts of experience. Although the “social turn” in academia has begun to exert its influence within SLA, narrative research nevertheless remains an underutilized approach and language-learner narratives are still looked upon with suspicion by some in the field.

Narrative Development in Second Language Acquisition: Oral and Written

M. SAGRARIO SALABERRI

Narrative can be defined as the representation of a series of episodes or events that form the basis of a story; in Labov's words (1972, p. 359), it is "one method of recapitulating past experience by matching a verbal sequence of clauses to the sequence of events which (it is inferred) actually occurred." Narrative development can be understood as a joint process of event comprehension and language production (Berman & Slobin, 1994). Narratives can be either in oral or written form; they can be personal, third person, or fictional and constitute "the main means by which we interpret, represent and communicate life experience and its personal significance" (Trabasso & Özyürek, 1997, p. 269). The turn to narrative in social science research emerged from the works of Bruner (1986) and Polkinghorne (1988), among others, and this theorizing model was rapidly followed by empirical research in varied fields such as psychology, cultural studies, and sociology. Over the last decades, studies of narrative development in monolingual and bilingual speakers have made great contributions to the field, and narrative methods have been widely used in studies of second language acquisition (SLA) as a means of analyzing individual and social development.

Components of L2 Narrative Development

As a form of communicative development, narratives involve opportunities to communicate orally or in writing, and also for the conceptual understanding of the L2. The definition of components of narrative development can provide insights into L2 development as a conceptual process and can also help to establish L2 teaching goals which are not just aimed at communicative competence but communicative development, to be understood as "the process of constructing meaning for others and the self" (Negueruela, 2008, p. 197).

An interesting proposal to describe components of L2 narrative development comes from Pavlenko (2007), who identifies the following components of narrative competence: structure, evaluation and elaboration, and cohesion. These refer to oral narratives but if we consider that "writing systems create the categories in terms of which we become conscious of speech" (Olson, 1995, p. 119), then oral narratives can be taken as a reference to define components of narratives in general.

The first component is the knowledge of narrative structures that are conventional in the target language, and the ability to use them appropriately in a context. In the field of SLA, studies of L2 learners' narratives have revealed that when L1 and L2 share similar narrative structures, learners use appropriate narrative structure in the target language stories (e.g., Verhoeven & Strömquist, 2001).

The second component is evaluation and elaboration. Elaboration involves the appropriate and rich use of lexis, figurative language (not easy to achieve in an L2), reported speech, imagery, and description. The function of evaluation is to make the point of the story clear and to make explicit why it is told. It includes the use of intensifiers, modal verbs, negatives, repetition, evaluative commentary, embedded speech, and comparisons with unrealized

events (Labov, 1972). Narrative styles in different speech communities may call for different strategies of elaboration and evaluation.

The third component is narrative cohesion, a semantic notion that refers to relations of meaning within the text (Halliday & Hasan, 1976). Cohesion is normally described with regard to two broad categories: grammatical cohesion and lexical cohesion, although cohesion can also be seen as created by intertwining lexicogrammatical patterns. The types of grammatical cohesion are reference, substitution, ellipsis, and conjunction. Lexical cohesive devices are divided into two main categories: reiteration and collocation. Cross-linguistic and cultural differences can be observed in the use of cohesive devices such as reference or conjunction.

Oral and Written Narratives in L2

The acquisition of a second language affords opportunities to participate in a new culture, in a new society, and this involves acting according to the new norms and sharing them in a new "textual community," defined by Stock (1983, p. 294) as "a group of people who have common understanding of a text, spoken or read, and who organise aspects of their lives as the playing of a script." In that respect, narrative texts constitute symbolic systems that can be expressed through oral or written codes, and through which members of a community can construct meanings.

Traditionally, an ideal written system has been understood to be a complete representation of an oral system and this view has affected the processes and methods of teaching literacy. An opposite view can be taken if we look at writing as a model for speech, considering that writing systems provide the concepts and categories for thinking about the structure of spoken language (Olson, 1995). In this perspective, writing has an influence on cognition and consciousness, providing a model for speech and a frame for thinking about what is said, although certain cultures have the tradition of narrating stories orally without relying on a writing system. It is through writing and reading that people become able to understand the logic of general and abstract concepts termed as "scientific concepts," part of which are both linguistic and metalinguistic concepts (Brockmeier, Wang, & Olson, 2002).

The suggestion that writing not only allows new things to be done, but also turns speech and language into objects of reflection and analysis forms part of the Vygotskian view. In fact, language becomes more visible to children or adults when they encounter literacy, developing the capacity to produce and read written texts and increasing their awareness and control (Lantolf, 2008). Written narrative thus changes the consciousness of writers, as historically happened with the development of writing systems (Olson, 1995).

Most L2 narrative studies have been limited to oral narrative discourse, with less attention being paid to written narrative discourse. Considering that narrative discourse is language specific (Berman & Slobin, 1994) and that there are important differences in the cultural conventions used when constructing stories, an area of inquiry has been how L2 learners' native language and culture affect narrative production in L2 and which areas of difficulty L2 learners face in producing extended discourse. Cross-cultural and L2 studies on oral narratives such as the one by Nakahama (2009) have shown the influence of L1 patterns on narrative discourse production in a L2. In fact, learners seem to use patterns derived from their first language to signal temporality, space, and direction.

In the field of written narratives, the study by Kang (2009), for example, has provided evidence that foreign-language learners of English do not use reference forms in extended L2 narrative discourse, which is attributed to the L1 specific reference conventions. L2 learners also show limitations in the production of cohesive written narrative discourse,

since it requires the use of specific linguistic properties that mark textual cohesion and written register. In narrative, order and coherence are applied not only to linguistic discourse, but also to visual and iconic forms such as pictures, paintings, and graphic devices that symbolize a sequence of events that are told and not just named.

Research Methodology on L2 Narrative Development

Two basic types of elicitation procedures for research on narrative development can be identified: one is based on the use of vicarious narratives and the other is based on the use of autobiographical or personal narratives.

Vicarious narratives are fantasy stories which do not refer to the personal experiences of the teller and can be elicited through verbal and nonverbal prompts. These narratives are described by Berman (2004, p. 262) as “the verbalization of graphic representations of non-veridical, fictive sequences of events” and differ from the reconstruction of real-life events. Perhaps the best-known story used in this type of research is “Frog, where are you?” (Mayer, 1969), popularized by Berman and Slobin (1994), but other tools include fictive stories based on short picture series or films. Using these prompts provides advantages like uniformity of content across the narrators that participate in the study, and low cognitive load imposed by the task, which makes it ideal for the elicitation of narrative talk. Studies that analyze narratives elicited with these procedures, such as those reported by Verhoeven and Strömquist (2001), normally use quantitative analysis.

Personal narratives are stories of personal experience. They can be spontaneous or elicited through verbal prompts and can be used not just to answer questions about narrative development but also to study the construction of the self. SLA is a process through which we become members of a particular community and this involves the attempt to adapt the self into a new context, a new world, and the development of “the ability to communicate in the language of this community and act according to its particular norms” (Sfard, 1998, p. 6). In that respect, narratives are not just individual productions, but are shaped by cultural, social, and historical conventions.

Research Results about the Development of L2 Narrative Skills

Languages differ across speech communities in structure, rhetorical styles, storytelling conventions, and devices and, as a result, narrative development is language specific. In this section, for the purpose of illustrating research and findings on L2 narrative development, English and Spanish as a second language have been taken as a reference.

Because narration is normally in past time, most of the research on second language narrative is concerned with the acquisition of past tense morphology, although scholars have started to investigate other aspects like the expression of emotion in narrative or storytelling skills. Some studies have worked on the hypothesis that narrative structure plays an important role in the acquisition of L2 past tense morphology. Liskin-Gasparro (2000, p. 831), for example, has found that past time morphology seems to appear in the foreground first and much later in the descriptive background. Taking narrative structure as an environment for the acquisition of tense/aspect, Bardovi-Harlig (1995) suggests a developmental pattern in the distribution of tense/aspect morphology with respect to narrative structure and argues that much of the variation stems from the level of proficiency of the learners.

As regards language proficiency and its relation to narrative competence, the study carried out by Montanari (2004) with English-Spanish bilingual children at different levels of proficiency shows that children fail to produce coherent and cohesive narratives in

L2 because of their lack of linguistic resources. In fact, limited proficiency in L2 has an influence on the lack of temporal and structural organization in L2 narratives. On the other hand, evaluation seems to be proficiency independent and learners were capable of evaluating their narratives. Aspects like lack of vocabulary and lack of basic fluency can also hinder the transfer from L1 to L2, which has been an object of study in narrative development. Taking into consideration that narrative development is based on the progression from use of the language at sentence level to use at discourse level, one of the challenges for L2 learners in developing their ability to tell stories is to provide background information, which seems to be the result of advanced proficiency in the target language.

An important component of narrative evaluation and elaboration is the use of lexis and figurative language, including metaphorical competence. Some studies have been carried out to analyze the use of lexical concepts such as privacy and emotional language in L2, providing evidence that new lexical concepts can be used in situations of cultural immersion, and that the new concepts not only influence L2 but can also have an impact on L1 performance. The appropriation of concepts from a new culture on the part of individuals, and how this is reflected in narratives, has been the focus of attention in several studies (e.g., Pavlenko & Lantolf, 2000).

An area of increasing interest is gesture and its relation with language in general and narrative in particular. Speech and gesture are integrated and express two aspects of thought: that is, visual and verbal components of communication form a unity and contribute to the expression and formation of meaning. In the framework provided by Slobin (1996), speakers of a particular language have a peculiar form of “thinking for speaking” (TFS) and, as a consequence, the acquisition of a second language involves a different TFS. Recent contributions in the field of SLA have focused on how motion, path, and manner are encoded in narratives in L1 and L2, and whether L2 learners shift from L1 to L2 patterns of TFS (e.g., Stam, 2006). In particular, data regarding gestures depicting motion have been provided on the construction of narratives by L2 speakers of English and Korean (Choi & Lantolf, 2008), or between English and other languages, and show how their narratives were constructed differently. Embodiment is considered to be fundamental to cognitive development as gestures and their corresponding language patterns index ways of conceptualizing reality. The interface between gestures and other elements of narrative, such as expressing time, place, space, scene setting, etc., constitute aspects that will require further research.

The Narrative Mediated Mind

Mediation is a core concept in sociocultural theory (SCT): the relationship people have with the world is not direct but mediated by artifacts, concepts, and activities. Cultural means have been developed throughout history to mediate between people and objects, be they physical or mental, and the most powerful means is language. Narrative texts as a form of language are cultural artifacts which constitute a means to regulate our own world, the external world, and each other’s social and mental activity. There are essential concepts in SCT such as the zone of proximal development (ZPD), mediation, and internalization that are closely linked to L2 development and also to L2 narrative development. The language-mediated mind, or more precisely the narrative-mediated mind, is not understood as information processing but as mediation through symbolization.

The first contribution of SCT in the field of SLA, and with a focus on oral narratives, which are both a form of language and a tool to foster development, comes from Frawley and Lantolf (1985) who showed that language not only relates a story but also functions as a means of regulating the thinking process as the narrative unfolds in real time. Narratives

have also been used in some studies to analyze inner speech, private speech, and gesture (Frawley & Lantolf, 1985; McCafferty, 1994; among others). Some findings have shown that lower-proficiency L2 students produce private speech utterances more frequently, which is interpreted as a signal of a lack of self-regulation. Also, L2 speakers use the progressive form in narratives to signal object regulation and describe events of the story as immediate, while they use the simple past to narrate the events of the story from a distal perspective (McCafferty, 1994).

When participating in new textual communities, the narrative plot that imparts coherence and cohesion to our narrative texts changes to make sense of our own and others' actions. In a general sense, literacy, which involves narratives, can be understood as the progressive participation in new textual communities. An example of the need to construct a new narrative plot when participating in a new culture is the case of Eva Hoffman, interpreted by Pavlenko and Lantolf (2000) together with other autobiographical texts. They look at the reconstruction of identities and how their life stories are retold, identifying stages in the process of moving from one culture into a different one. These views on narrative development illustrate the importance of new concepts in the transformation of inner organization.

Recent studies have focused on dynamic assessment incorporating narratives as a tool to capture development in action. In the framework of SCT two indicators of development can be identified: changes in the quantity and quality of mediation needed to help learners perform appropriately, and a learner's ability to transfer what has been appropriated through mediated interaction to new circumstances (Poehner, 2007).

Challenges and Directions

As Bruner (1991) argues, the mind structures its sense of reality using mediation through "cultural products" like language and other symbolic systems, and narrative is one of these cultural products. SLA provides opportunities to take part in a new reality and culture, and to reconstruct ourselves. In this view, narrative texts are cultural tools that act as windows to the way people reenact their identity and their world, so that the description of narratives as participation in culturally organized practices is a field of interest for the future—and also the relationship between narrative and imagination, since minds are tools to create new worlds.

At the same time, narratives are not simple data that can be analyzed in isolation, and future approaches to narrative development need to take into account the co-constructed nature of narrative and the dependency relationship between narrator and audience in the act of narrating. Our narrations vary enormously depending on the nature of the listener or reader (ourselves, a friend, a researcher, etc.).

Approaches to narrative development need to consider that even though learning and development are related because both processes originate in socially mediated activity, and although development occurs as part of learning activity, not all learning activity leads to development. Developmental processes must be seen as the formation of new semiotic tools that involve changes, are transformative and unpredictable, and vary according to the nature of interaction among all the elements of a system (Larsen-Freeman, 2008; Negueruela, 2008).

Finally, other areas of interest might include cooperation between mediators and learners to identify individuals' potential narrative abilities for the future—that is, processes that are developing and will have an impact on future literacy or future narrative success in contrast with what an individual can do alone in the zone of actual development.

Conclusions

Different views can be taken on narrative development, from the most formalist ones with a focus on the formal structure of narratives to other views that look at the symbolic content of narratives and how people use narrative for diverse modes of symbolic action. Some studies rely more on recall of preselected stories and judgment tasks rather than spontaneous stories that can avoid the precise specification of concrete elements. The understanding that the human mind is mediated and that, as happens with other types of cognition, narrative as individual cognition emerges through activity that is socioculturally mediated provides a different way of ordering experience and constructing reality through stories.

Narrative Discourse

MICHAEL BAMBERG

This entry brings two lenses into fusion and, by use of a few brief illustrations, documents what narrative discourse is able to contribute to the general field of applied linguistics. On the one hand, we are modifying discourse by looking at discourse through the lens of a special type or genre of discourse—the generic form of narrative and the functions it serves. On the other, we bring a discursive perspective to narrative, that is, we view narrative as a discourse mode—in contrast to viewing it as a text type or a literary genre (see Fludernik, 2000), or as a general formula for “experience” or “life.” We will begin with some clarifications of narrative—first along formal and structural lines, followed by considerations how narratives are contextually and functionally put to use, feeding into a brief illustration within two practical fields (retardation and Alzheimer’s) in which narrative discourse has been analytically explored and applied.

Narrative in Discourse—Forms, Structures, Contexts, and Purposes

Narratives, as discourse modes, come in different types and formats and are put to use in different contexts, and often for quite different purposes. What falls under the header of narrative ranges from folk or fairy tales and oral histories to eulogies at funerals or sharing time recounts in preschool about what happened yesterday, to personal stories shared in institutional or more private conversational settings such as accounts in the courtroom, in therapy sessions or in research interviews, to bedtime stories, and to potentially more personal stories around the dinner table or in private (though sometimes also public) disclosures. Varying quite drastically in content, these storied discursive genres nevertheless share certain family resemblances in terms of conventionalized discursive histories that set them aside and constrain the kinds of functions for where and how they can be put to use. In addition, speakers may choose to center their story exclusively on others (as in fairy tales, certain bedtime stories, eye-witness reports in court, or in gossiping about neighbors), include themselves to a degree (as in eulogies, roastings or wedding speeches), or make the self the almost exclusive topic (as in self disclosures in therapy or in research interviews, or as in confessions).

With regard to what is special about narratives, it is commonly held that narratives serve the purpose of passing along and handing down culturally shared values of what is considered good and aesthetically valued, so that individuals learn to position their own values and actions in relationship to established and shared categories and thereby engage in their own formation process as persons. It seemed to have been the recognition of this function that inspired a good deal of the *Narrative Turn* in the social sciences and humanities, where narratives have gained a special status as a privileged access mode in the investigation of personal experience (see however Atkinson, 1997). In the wake of working with narratives over the last decades, narratives have proven to highlight and bring to the fore the relevance of differentiating and integrating a sense of self in the identity formation processes of institutional and personal continuities (Bamberg, 2011a). However, at the same time, it is through those narratives that counter established norms and conventions that

people can identify discontinuities and define “new” positions, thereby contributing to change and transformation—first of all locally and contextually, but also potentially more generally in terms of larger societal transformations that even may take on global dimensions. The question whether narratives represent and simply mirror continuity and change or whether they are viewed as facilitating and maybe even instigating change and transformation is one that will be picked up again further below.

Building on its function to position a sense of self vis-à-vis culturally shared values and existing normative discourses, narrative discourse claims a special status in the business of identity construction. In narratives, speakers typically make claims about characters and make these claims (that are said to have held for a there-and-then) relevant to the here-and-now of the speaking moment. In other words, whenever narrators in their discourse rely on narrative resources, they connect some spatio-temporal coordinates relevant for a character in the past (or an imagined future) with a different time-space zone (usually one that is relevant to the participants in the here-and-now of the interactive situation). And mapping out this space and navigating it in terms of what has changed and what remained the same is what makes narratives one of the cornerstones for the construction of identities; irrespective whether these are the identities of institutions, groups and communities (real or imagined), or individuals (again: real or imagined) (see Bamberg, 2011a; Bamberg, De Fina, & Schiffrin, 2011).

Summarizing thus far, it seems that the attempt to fuse a narrative with a discursive lens (and vice versa) has the potential to bring issues of constancy and change into sharper focus and at the same time highlight particular positions that are taken as more personal or individual stances vis-à-vis commonly shared and circulating positions that are floating within communal discourse practices. Proceeding with sharpening these two lenses, two types of analytic work with narratives should be distinguished: (a) approaches in which discourse is underdetermined and narratives are analyzed as monologues in terms of what they are about and as units of structural form; and (b) approaches in which narratives are overdetermined and equated with experience and life, whereby discourse becomes the mere expression of *narrative thinking* or *narrative being*. A combination of these two ways of working with narrative analytically would provide an alternative that makes use of the resources and analytic procedures that both approaches have to offer.

Caveats: Underdetermining Discourse— Overdetermining Narrative

Typically, the first kind of approach builds on a notion of narrative discourse as representing and referring to events or happenings of the past and as minimally connecting two propositions that represent two temporally bounded events (see Labov & Waletzky, 1967/1997, and Bamberg, 1997, for specifics). For lack of a better term, and in contrast to the next section where language is taken as derived from and working *on top of* conceptual structures, the terms *language-on-the-ground* or *bottom-up approach* are chosen here. The events depicted accordingly have typically taken place in the past, but can be ongoing in the present (as in a coverage of an ongoing event), or fictitiously take place in some future. Discourse here is defined, following the original definition of Zellig Harris (1952), as larger than the clause; and its analysis is concerned typically with the cohesive ties between the clauses, that is, how events are connected in speech, forming a (back)ground against which something else can begin to stand out as new, as relevant or foregrounded. These approaches start from the clause as the basic unit of analysis and analyze how connections bring about what a story is considered to be about: its content—its theme. Analysis focuses typically on what is *old* (already shared) and *new* information, what is the *topic* and what is being *commented on*, what is the *background* and what is *foregrounded*, the *theme* versus the *rheme*,

and how *agency* constellations emerge at the content-level of stories that are interpretable as protagonists and antagonists, as villains and heroes, as perpetrators and victims. What is deemed to be relevant (to the speaker—personally, or to the context in which the story is embedded) is part of a *speaker stance* that is signaled in how the information is presented at the clause-level and tied into the thematic whole of the discourse unit.

A similar approach, also starting off from the referential and representative functions of discourse, focuses on speakers and hearers bringing to narrative discourse a particular kind of cognitive repertoire (in the form of a *story grammar*) (see Mandler & Johnson, 1977; Stein & Glenn, 1979). This enables them to work from a prototypically mentally represented structure of storied discourse units (often called *plots*) down into their components—their beginning, middle, and end. These component parts are said to consist of an (optional) *abstract*, followed by an *orientation* (or *setting* or *exposition*), followed by a *complication* (also called *problem* or *crisis*), maybe an action or action orientation toward a resolution, that—if acted upon—results in the *resolution* (or occasionally *failure*), which then is ultimately followed by a *coda* (or *closure*). The *orientation* takes the story recipient to the there-and-then where the action takes place—and where characters emerge as protagonists and antagonists—while the *coda* leads the audience back into the here-and-now of the telling situation. Engaging in narrative discourse by starting from conceptual units that are fleshed-out linguistically in a second step that has been visualized in the form of a top-down analytic procedure, where language is conceptually driven.

To summarize these two approaches, while the *language-on-the-ground* approach views the textual whole in a bottom-up configuration, emerging from the use of linguistic devices that form clauses and index how they are to be understood as text, the cognitive approach works the other way around: It starts from the textual whole that is assumed to be conceptually available—working down to the bottom parts to be filled in (*fleshed-out*) in terms of discursive devices. Both language-based and cognitive approaches deal with discourse primarily as representations of contents—and from here have an option to venture into the audience-designs of these texts, but only as a second, subsequent step. Both approaches also work with the notion of a speaker as positioned vis-à-vis an audience and fashioning the text from a point of view that is—at least to a degree—colored by affect and value orientations. However, in spite of laying bare some important microlevel components as the building blocks of narratives, the interactional function of narratives in discourse settings (i.e., why they are shared and surface here-and-now) is not fully exploited and leaves the exploration of narrative discourse as textual units underdetermined, as if speakers have narratives in their heads—which can best be tapped into in their purest form when speakers speak (monologically) to themselves.

In contrast to underdetermining discourse and its value for shedding light onto narrative as a discourse mode, approaches that equate narrative with life have gone the other way and resulted in an overdetermination of narrative. Starting with original claims of theoreticians who pointed toward the potential of narratives for the interpretation of lives (particularly life stories and life-event stories—e.g., *The Narrative Study of Lives*, see Josselson & Lieblich, 2009), a research branch has emerged that separates (told) narratives from discourse and posits narrative as an abstract and principled way of making sense of the world (as *world-making*—see Bruner, 2001, 2003) and more strongly, as the designing and generating force for (meaningful) experience and living a meaningful life (see McAdams, 1993; Randall, 1995; Xu & Connelly, 2010). A number of critics have termed this tendency to overdetermine narrative a form of “narrative imperialism” (see Sartwell, 2000; Strawson, 2004; Phelan, 2005), while others have engaged in a campaign to reformulate this thesis in a way to preserve the contributions of narrative in analyzing identity and experience and merging it with *language-on-the-ground* approaches under a constructionist flag (see Bamberg, 2011b; Bamberg et al., 2011).

Naturally, and this is where both approaches can be transformed into one converging lens, narratives don't just empower or constrain their users with identity generating potential, just as narrative discourse does not take place in disembodied minds. Narratives typically are shared and performed between people and for (interactive) purposes—in situ and in vivo. Consequently, from a discursive perspective, particular attention needs to be placed on how and where identities and conventions from the past are confirmed and where and how they are contested (see Bamberg, 2004, 2011a). This space within the social dimension of discourse, that is, narratives-in-interaction as bodily performed, is the site to be explored with an eye on where and how the boundaries of traditional categories are conventionally handed down and tested out over time. In interaction, narratives form the location to try out, contest, subvert, and draw up new boundaries that, if reiterated and practiced over time, may result in constructions of alternative and new boundaries for new identity categories.

Summarizing thus far, and underscoring the contributions of narrative discourse as a research domain for applied language studies, it is the close link between narrative discourse and the construction of identity that opens up fields for exploration that go beyond traditional linguistic studies. If people make sense of themselves in their narrative practices (see Gubrium & Holstein, 2009; Bamberg, 2011c), then questions of *who-I-am* as a female, who was born in Switzerland, grew up in the Italian-speaking part of Switzerland (with a Swiss passport), living and working in New England (USA) for the last 30 years—as a therapist—as a Green-Card-holder, and as a mother of two girls who play soccer, practices a conservative form of Judaism, married to her lesbian partner who is a Catholic, and driving a Volvo station wagon open up as categories to be explored further; not only in terms of how these identities are expressed in isolation or combined; but in addition as exemplars of what it means to be Jewish *and* lesbian, or to be a Swiss Italian native speaker who lives in the USA, or to be a Volvo-driving soccer mom. As interesting (or uninteresting) as these identity constructions may be as research projects, and while it may be doubtful whether any of these categories may be tied into spatio-temporal coordinates of presenting a past that is made relevant for the present (if at all), it is narrative par excellence—as a discourse mode that offers insight into how these identities may be put to work in terms of a construction of a spatio-temporal past—that bears on the present here-and-now of its telling.

Narrative Discourse—Use-Inspired and Use-Inspiring

Since narrative discourse cuts through almost all dimensions of practical lives, it may come as no surprise that the fields to which narrative analysis has found entrance are manifold. Not only has it become a multidisciplinary endeavor, spanning across the humanities and social sciences into the realms of education, medicine and law, it is increasingly being used to do inquiry into interesting knowledge domains—such as the body, emotions, sex and sexualities, aesthetics, art, education and institutional organization, to name just a few. Particular kinds of experience have been opened up to closer inspection by way of analyzing the narrative discourse that is used to make sense of phenomena such as: marriage, weddings and divorce; emigration, immigration, nationality and globalism; menarche and menopause; loss of and relationships with loved ones—for example, parents, siblings, friends; life transforming (traumatic) incidents—such as illness, retardation, war, and rape; professional careers and trajectories, especially those of care providers and teachers; and last but not least, of course, the restoration of identity in (narrative) therapy.

Bringing a narrative dimension to discursive practices—and a discursive dimension to shed light onto narrative practices—does not automatically result in new or critical dimensions

of knowledge production, and neither does the merging of these two lenses directly (and positively) feed into new real-life practices or policy making. Rather, the impact of narrative research remains often unnoticed and hidden. For this reason, one domain of narrative-inspired discursive research is picked to illustrate which kinds of use-inspired dimensions may open up to be further explored. The domain chosen here is one where narrative discourse, particularly in its identity-building function, is threatened by mental retardation and memory loss.

In one of their examples of practical fields of doing narrative discourse research, Gubrium and Holstein (2009) take their readers into the narrative practices of a family with a daughter who has been diagnosed as severely mentally retarded. And although the transcripts read to the outsider as if the daughter is communicatively inapt and not reciprocating, Gubrium and Holstein can document how stories unfold collaboratively between the participants who construct Mary as an “accountable subject who has sensible judgment and distinct preferences” (p. 157). A very similar point is documented in Goodwin’s (2007) analysis of storytelling practices in multiparty interactions with a participant who, because of a severe stroke, has a verbal repertoire of only three words: *yes*, *no*, and *and*. The contribution of studies that explore retardation not solely as a problem of individual consciousness but as one that is situated in narrative interactive practices has led to rethinking issues around “quality of life” and how to train care personnel and advise family members in their care work with patients.

Turning to threatened identities due to memory loss, Hamilton (2008) uses the narrative lens to understand better the “narrative traces” in Alzheimer’s patients’ discourse; and how such “traces” can be used in vivo and in situ interactions to give patients “a chance to hold onto a robust and varied sense of self narratives . . . that serve as the stuff of enduring personal experience narratives” (p. 77). Similarly, Hydén (2010) can be seen as building on Hamilton by stressing that narrative meaning and narrative identity are the product of interactive work.

While the use-inspiring orientation of these types of narrative research may often not directly translate into interventions or immediate practical applications, they certainly contribute to the debunking of accepted wisdoms, here assumptions of retardation and Alzheimer’s as purely individual deficits that have to be encountered and treated as such. However, the four studies presented here in short form entail implicit recommendations for change as well as a potential empowerment of those involved in daily interactions with those who live diagnosed and stigmatized (see Hamilton, 2008, p. 79).

Nation

JOHN E. JOSEPH

Languages and Nations

The term “nation,” as opposed to “state” or “federation” or “territory” or other related terms, implies the existence of a people united either by common ancestry or some other deep cultural bond. Although the different natures of the bonds mean that nations themselves are never identical in makeup—indeed, in everyday discourse “nation” can be interchangeable with “state”—they are spoken of and imagined as if all still fit the historical concept of nation that underpinned their formation from the early modern period onward.

The concept of the nation, and the particular features that mark one nation off from another, have always led back to language as the most fundamental of all cultural differences. The analysis and teaching of languages has inevitably been bound up with projects to create and spread belief in some version of a nation—though 20th-century modernism, a movement defined by its “deliberate break with classical and traditional forms or methods” (*OED*), allowed linguists and language practitioners to go temporarily into denial about the fact.

National language policies have proven effective in proportion as they take account of the beliefs, desires, and aspirations of the people affected (see Wright, 2004; Joseph, 2006). In determining where the boundaries of a nation lie in terms of both population and territory, and whether a given individual belongs to a particular nation or not, the matter of what language is spoken has long seemed to offer the surest and most objective criterion. Yet no nation has ever been linguistically homogeneous—bilingualism and multilingualism have always been the norm for most societies—and the way in which languages spread is a cultural matter disconnected from genetic ethnicity.

There is, then, a gap between the reliance on language to define the nation, and the heterogeneous nature of language itself. The gap is filled by ideology and myth, and it is here above all that is located the importance of language (or rather, of what people believe about language) for nationalism. Renaissance Europe knew this both through its religious and its philosophical heritage. The Bible taught in Genesis 10:5 that, after the Flood, the grandsons of Noah spread across the earth, each forming his own nation, with its own language. The ancient pedigree for empiricism in the early modern period led back to Epicurus, who believed that different languages reflected the different physical makeup of the nations who spoke them.

Revolutions and imperial expansion over what historians call the “long 19th century” (the 1780s through World War I) brought about a second phase in the conceptualization of nations, with language taking even more of a central role in order to legitimize the creation of states which combined a number of nations in the traditional sense, often nations which had long been hostile to one another. Particularly in German lands that were being taken over by Napoleon, writers such as Fichte, drawing on earlier work by Herder, strove to locate resistance in the belief that people who share a language share a national spirit or soul, and have a natural right to occupy a state with boundaries corresponding to that of their linguistic nation.

This ideology, which in recent years has been referred to as “language nationalism,” would still be the guiding principle when the map of Europe was redrawn at the end of World War I. It would reach its culmination in Nazi Germany, with its project to restore the Aryan nation to primal purity by eliminating foreign elements such as Jews, whose racial difference was established principally on linguistic grounds, according to the research of Hutton (1999).

Language nationalism is a double-edged sword. It gives meaning to people’s lives by marking and manifesting their identity and allowing them to bond with those who share that identity. But it does so at the price of making it impossible to ignore differences vis-à-vis other groups, thus helping to keep opposition and hostility alive. The “one nation, one language” doctrine, Romantic and oversimplified as it was, allowed many oppressed peoples to gain their independence in 1919, in some cases after centuries of foreign domination. Yet it was linked to the doctrines that fed into “scientific racism” and were ultimately used to justify genocide.

Language, Knowledge, Religion, and Nation

In Europe, for over 1,000 years, “language” referred in the West almost exclusively to Latin, and in the East to Greek. The vernaculars which ordinary people used with one another in everyday discourse were recognized to exist, but not to have the status of “a language.” The fact that they differed from village to village made them appear unsuited to functions involving the transmission (through space or time) of real, permanent *knowledge*. Even after this way of seeing things began to change in the late medieval period, the basic one-language model remained in place: one dialect came to be a standardized form of the national vernacular. This process took a long time to transpire—indeed it is still transpiring—and may never reach completion, as certain symbolic functions in law, religion, and education continue to be reserved for the classical languages.

Initially, the main obstacle to seeing vernacular ways of speaking as languages was that Latin and Greek had “grammar,” as witnessed by treatises on the subject, and the variation in them was controlled by the fact that they were “dead,” since even Greek did not have native speakers of its classical form. This fulfilled (or perhaps determined) the expectations of what a language had to be, given the exigencies of maintaining and transmitting knowledge as noted above. When a person’s enlightenment was revealed by one’s control of the Latin terminology for the highest philosophical concepts, it was difficult to imagine such knowledge being held and safely transmitted in a vernacular that was itself “irregular” in two senses, exhibiting great variation from locale to locale (and even in the usage of a single individual), and lacking the formalized rules of a grammar book.

This is why, when Dante set out to imagine (or in his word, “discover”) an “Italian language” at the start of the 14th century, the term he used for it was *volgare illustre*—*volgare* because it belonged to the ordinary people as well as to the learned, *illustre* because it could be the vehicle of enlightenment, of the highest knowledge. This, he realized, would take some work. *De vulgari eloquentia* laid out the work plan, and the *Divina commedia* then performed the result. Italian became the model that was followed in the creation of other “illuminated vernaculars.” Once Dante had demonstrated that a vernacular could be not only a language, but a language of enlightenment, and could form the basis of a specifically *national* literary culture (even where the political nation did not exist, as, again, Italy would not for centuries to come), a new era opened in the politics of language in Europe. The first effect was simply that writing in the vernacular became semi-respectable, and more people—though still a small minority—began doing it. With movable type and print capitalism in the 16th century, it emerged that the potential market for books in the

vernacular was more sizeable (though less prestigious) than for books in Latin. Profitability accelerated if large print runs were sold, which could happen only if a large audience could read the language.

This brought a new twist to the old language–power–resources nexus. While scholars and clergymen concerned themselves with enlightenment in the language, which the borrowing of words from Latin and Greek gave the impression of increasing, publishers knew that a certain economy between learned and popular language was necessary if the readership was to be wide enough to make a book profitable. Without profits, funds could not be raised to publish any more books, since those with the funds would invest them elsewhere. But something else was happening in the 16th century: the “emergence” of the concept of the nation. I put the word emergence in quotation marks because it suggests a nondeliberate process, but in fact it is clear from the documentary record that vast efforts were undertaken by governments to get the populace to buy into the idea of the nation. The “national language” was an obvious concept to seize upon to promote belief in the internal unity of the nation and its difference from its neighbors and rivals—at the most fundamental level, that of knowledge itself. Even if these ideas were not clearly articulated until the early 19th century (see for example Joseph, 2004, pp. 109–15 on Fichte), they are implicit in much of the writing and cultural activity surrounding language from Dante through to the end of the 18th century—and nowhere more so than in those mostly northern European countries which took the nationalist route of breaking from Rome to form their own national church.

Myhill (2006, p. 13) has put forward the thesis that “If a pre-modern national church had been established (in practice all such churches to be discussed here were established by 1600), then even in modern times national identity based upon religious affiliation has proven to be more important than identity based upon spoken language.” This is either because “the group was secure in terms of its political and military sovereignty but wanted to emphasize its religious sovereignty as well,” or because “the group was in a tenuous position, politically and militarily, in terms of maintaining its independence or autonomy, and wished to emphasize its distinctiveness by making its separateness organizationally explicit.” This thesis holds potential for future research, though at this stage Myhill’s presentation of facts may be too selective, and an account which allows the same result either because a group is secure or because it is weak is explanatorily unsatisfying.

Writing the Nation

The beginnings of modern political nationalism in early modern Europe faced a fundamental problem: on the ground, nothing corresponded to the “national languages” that nations ought to possess, according to the Bible and the Epicureans. The spoken vernaculars were a patchwork of local dialects so diverse that one did not have to travel more than a day or two from home before ceasing to understand or be understood, particularly if a mountain or major river had to be crossed. The business of church and state, and anything that required a written record, was with few exceptions done in Latin, which, being pan-European, did not qualify as anyone’s national language. And yet, all that “language” proper was taken to mean was defined by Latin, with its grammars, its rhetorical tradition, its literary heritage, and its status as the official scriptural language of Western Christianity.

Linguistically equipping nascent nations required creating for their vernacular speech all those cultural embodiments that Latin possessed. The first obstacle was the formal diversity. Latin itself was pronounced differently in different parts of Europe, yet by cultivating a high literary and rhetorical style, modeled on classical authors, its written form

was kept aloof and its diversity limited. For this to be achieved with a national language, a primarily written form would need to be fixed, and there was no lack of educated men eager to put the dialect of their own region forward as the basis of that written language. It would, after all, mean that the nation would look to their region as its spiritual center, and to them personally as its cultural authorities.

The ideology of language nationalism holds not only that a people and its language are coterminous, but that the language embodies the soul of the people, whose cultural responsibility it is to keep the language pure, probe its history, and ensure that its "correct" form is spread throughout the population as much as possible. In fact a little historical evidence could be stretched a long way; Smith (1998) has emphasized how much of the effort of nationalism construction is aimed at reaching back to the past in the interest of "ethno-symbolism." As Hobsbawm has pointed out, the national standard language is, like the nation itself, a discursive construction:

National languages . . . are the opposite of what nationalist mythology supposes them to be, namely the primordial foundations of national culture and the matrices of the national mind. They are usually attempts to devise a standardized idiom out of a multiplicity of actually spoken idioms, which are downgraded to dialects . . . (Hobsbawm, 1990, p. 51)

Hobsbawm defines the standard language as "a sort of platonic idea of the language, existing behind and above all its variants and imperfect versions" (p. 57). A "mystical identification of nationality" then occurs with this idea of the language, an identification Hobsbawm considers "much more characteristic of the ideological construction of nationalist intellectuals, of whom Herder is the prophet, than of the actual grassroots users of the idiom. It is a literary and not an existential concept" (Hobsbawm, 1990, p. 57). It should be noted, however, that while it may be *historically* true that the national/standard language is the property of nationalist intellectuals rather than of ordinary users during the period when it is initially being constructed, this ceases to be the case once it enters the educational sphere, and once education is widespread. The linguistic ideology then becomes common national property, as least as likely to find firm belief among the working classes who do not control it as among the upper classes who do.

Nations and Languages as Imagined Communities

The nation as reconceived since this period has been defined by Benedict Anderson as an "imagined political community."

It is *imagined* because the members of even the smallest nation will never know most of their fellow-members, meet them, or even hear of them, yet in the minds of each lives the image of their communion . . . Nationalism is not the awakening of nations to self-consciousness: it *invents* nations where they do not exist. (Anderson, 1991, p. 6)

As with the "discovery" of a national language, a crucial part of this inventing or imagining of a nation is the creation of a belief that the nation has *not* been invented. Its invention must, in other words, be forgotten. For if invented, the nation might be perceived as merely artificial, arbitrary, contingent in character, thus making its validity seem very shallow indeed. Instead the myth must be made that the nation is a *natural* entity, with a deep-rooted authenticity that is being rediscovered. If the nation in question has not existed as a nation during the whole of recorded history, then its legitimizing myth will be extended back into prehistory as far as needed to establish its claim to authenticity. Anderson goes on to explain that the nation

is imagined as a *community*, because, regardless of the actual inequality and exploitation that may prevail in each, the nation is always conceived as a deep, horizontal comradeship. Ultimately it is this fraternity that makes it possible, over the past two centuries, for so many millions of people, not so much to kill, as willingly to die for such limited imaginings. (p. 7)

Both of the primary organizational structures which preceded the modern conception of the nation, the religious community and the dynastic realm, were vertical rather than “horizontal” in arrangement. Authority flowed downward from God to the supreme human authority, whether religious or secular, and thence outward to the rest of the community. A hallmark of modern thought was that these vertical hierarchies came to be seen as overtly mythical, serving the interests of those at the top and oppressing those at the bottom. And so they came to be replaced, in part, by the “horizontal” nation of which every citizen is, in a sense, an equal member. The fact of their inhabiting a contiguous territory becomes essential, overriding differences of religion, culture, class, and so on. Yet how then to motivate people to fight, to the death if necessary, on behalf of the nation—often against other members of their own religion, for example? This is why the new mythologies were required.

It has not been unusual for linguistic difference to be increased, particularly through writing, in order to create two distinctive national languages where, from the modern linguist’s point of view, there is actually one single language, though the speech communities involved insist that they differ. A classic case is that of Serbian and Croatian, which are mutually comprehensible, differing on a level comparable with dialects of English. But they have undergone literary development in a way designed to maximize the appearance of difference between them. Serbian, the language of a majority Orthodox Christian nation, is written in the Cyrillic alphabet, as Russian is. Croatian, the language of a majority Roman Catholic nation, is written in the Latin alphabet, as English is. Linguists often prefer to speak of “Serbo-Croatian” as a single language, on the grounds of the lack of linguistic distance, but this is not a concept one often encounters among Serbians or Croatians, for whom the religious and attendant cultural differences have remained strong enough to provoke war and “ethnic cleansing” as recently as the 1990s.

An earlier example is that of Irish and Scots Gaelic, universally recognized as two distinct languages, with the Ethnologue database listing as well “Hiberno-Scottish Gaelic,” identifying it as an “Archaic literary language based on 12th century Irish, formerly used by professional classes in Ireland until the 17th century and Scotland until the 18th century.” But people in the Gaelic-speaking areas of Scotland up until well into the 17th century recognized just one language, which they called Erse (Irish). Only around that time did the desire arise to have *their own* authentic Gaelic, and some of those who shared the desire brought it into existence by deliberately writing Gaelic in ways that broke with the norms of what today, in retrospect, is called “Hiberno-Scottish Gaelic.” Ever since, the separateness of Irish and Scottish Gaelic has been more immediately apparent on the page than to the ear.

Literary development always extends distance and sometimes creates it, not just from other related dialects, but even from the dialect base of the very language that is undergoing the building-out process. In the end, though, so long as people *believe* that their way of speaking constitutes a language in its own right, there is a real sense in which it *is* a distinct language. They will probably find ways to “perform” their distinctive linguistic identity for the benefit of others, but ultimately what matters is the imagined community of their language and their nation.

In the second half of the 19th century, those Eastern European and Scandinavian nations that had lacked a well-defined standard language of their own acquired one—or two, in the case of Norway’s *Nynorsk* and *Bokmål* (the first based more on rural and the second

more on literary dialects), and Greece's demotic and *katharevousa* (puristic). Meanwhile, the older European standard languages, formed during the Renaissance, were subjected to a new wave of nationalistically motivated attempts at eliminating variation by establishing a single "correct" usage, based on scientific study of the language's history. This was the age of the great modern dictionaries such as the *Oxford English Dictionary*, the French Larousse, and their counterparts in every other major language. These same years witnessed the rise of the "history of the language" as a genre, following the plot of national histories, where the modern standard language is treated as the perfect expression of the national soul and its rise as an inevitable historical good. Those who contributed to its rise are portrayed as heroes, while anyone who tried to hold it back, either by sticking conservatively to Latin or by promoting a rival dialect as the vernacular standard, is shown up as a knave or a fool.

However, this new wave of standardization also saw attempts to promote other regional dialects that had lost out in the initial race to emerge as the national tongue. The *Félibrige* movement in the south of France was a particularly successful example. A new, standardized form of Provençal was promoted through the production of grammars and creative literature, notably by the poet Frédéric Mistral. Many others followed this example, in the Celtic-speaking areas of the British Isles and France, the Basque and Catalan areas of France and Spain, and in other regions throughout Western Europe. This new linguistic separatism would continue to flourish through the 20th century, though states would differ in the extent to which they would tolerate regional vernaculars or try to restrict them to private contexts. This was also the period in which the revival of Hebrew was being discussed and planned by European Zionists—though by no means were all of them agreed that Hebrew should be the national language of the eventual Jewish homeland. Attempts at standardizing Yiddish, Judeo-Spanish, and Jewish dialects of Slavic and other Semitic languages were also underway.

Outside Europe, in the Americas, Oceania, and South Africa, the period saw growing recognition of national varieties of Dutch, English, French, Portuguese, and Spanish, that could legitimately follow norms of their own independent of those of the European homeland. National language academies sprang up throughout South America in the last two decades of the 19th century. In most cases, what appear objectively to be very minor differences took on great significance as markers of national identity within the standard written language, which continued to be 99% identical with its European counterpart, even when, as in the case of Quebec French or Brazilian Portuguese, the spoken form of the language (except as used by the educated middle and upper classes) had become largely incomprehensible to people in France or Portugal.

In Asia, calls were heard for the traditional written languages, with their centuries or even millennia of venerable tradition, to be replaced with an alphabetic system, as modernizers looked generally to Western technological methods. These calls would meet with success in Indonesia and Malaysia, though not in all countries. For Chinese there was a particular obstacle to alphabetization. The system of characters transcended differences among the Chinese dialects, which are linguistically as distant from one another as are English, German, and Swedish. Alphabetization would have required the choice of one dialect as standard—a political and practical impossibility in China until the Cultural Revolution of the 1960s.

Modeling Language Nationalism

Various models have been put forward for understanding how language embodies national identity (see Joseph, 2004). During the decades of Marxist intellectual dominance, it was

inevitably seen as a manifestation of power. Starting in the 1970s, the social identity theory developed by Henri Tajfel moved away from such analysis, toward a quasi-structuralist identification of social identity as “that *part* of an individual’s self-concept which derives from his knowledge of his membership of a social group (or groups) together with the value and emotional significance attached to that membership” (Tajfel, 1978, p. 63). It focused on the relative hierarchizations that people seem instinctively to impose on ourselves, most particularly in our status as members of “in-groups” and “out-groups.”

Tajfel’s sometime collaborator Michael Billig went on to analyze the particular power of the half-unnoticed signs of identity that are spread and reinforced daily through the symbols on coins and flags and, indeed, in forms of language. He defines this “banal nationalism” as

the ideological habits which enable the established nations of the West to be reproduced. It is argued that these habits are not removed from everyday life, as some observers have supposed. Daily, the nation is indicated, or “flagged,” in the lives of its citizenry. Nationalism, far from being an intermittent mood in established nations, is the endemic condition. (Billig, 1995, p. 6)

Billig criticizes studies of nationalism for focusing too much on the strongly asserted nationalism that is typical only of a small minority of people, ignoring the banal nationalism that is part of everyone’s everyday life (strong nationalists included).

The idea is often encountered that in present-day “late modernity” we are experiencing serious challenges to the modern concept of nation, due to globalization, by which is meant the movement of people, capital, and ideas across national boundaries to an unprecedented degree. Serious historians of the subject maintain, however, that this is something of an illusion, brought on by the fact that the 20th century was a time of unusually high restrictions on trade and migration, and that what has happened over recent decades is a return to historically more normal conditions. The fact that nations have been able to regroup themselves in new national languages after having given up their traditional one testifies not to the weakening of the nation as a concept, but rather to its resilience and robustness.

National Language and English in India

VAIDEHI RAMANATHAN

This short entry focuses on a small cluster of issues relating to English instruction in India. While Hindi and English are recognized as India's national languages, this multilingual space has 20 other officially acknowledged languages (Assamese, Bengali, Bodo, Dogri, Gujarati, Kannada, Kashmiri, Konkani, Maithili, Malayalam, Manipuri, Marathi, Oriya, Punjabi, Sanskrit, Santali, Sindhi, Tamil, Telegu, Urdu), and it offers K–12 instruction as well as college instruction in the liberal arts in some of these “vernacular” languages. However, as with most educational systems, glaring inequities exist, most especially around opportunities available to students graduating from these divergent mediums of instruction. While ideologies around sustaining multilingualism and offering instruction in home languages are strong (being partially justified on the basis of leveling out the playing field for all learners), these separate tracks dovetail with larger sociopolitical divisions of class and caste in the culture. Globalizing surges, though, are changing some of these language policies, and in so doing are also contesting societal divisions. The following discussion partially sketches some inequities relating to the separate tracks of education, as well as what ideas around English and globalization are enabling in that area.

English Instruction in Vernacular vs. English-Medium School (and College) Settings

Most K–12 students in India get slotted into what are called “vernacular-medium” (VM) or “English-medium” (EM) tracks of schooling (see Ramanathan 2005 for a detailed discussion of inequities perpetuated by such tracking). Constitutionally, the Indian government promises the availability of an education in the mother tongue (in the 22 official languages) as well as an education in English. In the western Indian state of Gujarat the system for the most part works like this: English is introduced as a foreign language in Grade 5 in the Gujarati-medium classes, and Gujarati is introduced at the same grade level in English-medium classes. Hindi is introduced in Grade 4 and Sanskrit in Grade 7 in both mediums and all EM and VM students have to learn these until grade 12 (southern states in the country do not offer instruction in Hindi; neither is Hindi recognized as a “national” language, since it is not Dravidian and the south has long sought a “national” recognition for a Dravidian language). If policies existed in vacuums, this scene might be regarded as reasonably egalitarian; after all, students in both streams are becoming literate in several languages. But, as we know, educational policies and enactments of and around them, have rings of divisiveness and exclusionism around them (Shohamy 2006). Equity in this context—as indeed in many parts of the world—is directly tied to which kind of student is ready for college. Very many colleges in India (except for a few liberal arts colleges) are, for the most part, in the English medium, which means that students with vernacular-medium backgrounds (where they have had access to a few hours of English instruction a week) have to compete with their EM counterparts (for whom English is pretty much a first language) in colleges and beyond. Table 1 provides a very brief example of the very different “minimal levels of learning” (MLLs, or basic literacy skills) that VM and EM

Table 1 Divergent MLLs for GM and EM Students (from Purani, Salat, Soni, & Joshi, 1998, pp. 1–3; Purani, Nityanandan, & Patel, 1999, p. 2)

	<i>Excerpts from MLL from English textbooks used in the Gujarati medium</i>	<i>Excerpts from MLL from English textbooks used in the English medium</i>
Grade 5	<i>Writing:</i> Gains control of the basic mechanics of writing in English like capital letters, small letters, punctuation, writing neatly on a line with proper spacing Transcribes words, phrases and sentences in English Writes cardinals up to 50, telephone numbers, road signs Produces words and spells them correctly Writes numbers up to 50, telephone numbers, road signs	<i>Reading and writing:</i> Reading textual material and writing answers to questions based on and related to the text Reading and interpreting and offering comments on maps and charts Reading children’s literature and talking about it Writing paragraphs on given topics Reading and writing simple recipes Reading and interpreting labels on wrappers
Grade 7	<i>Reading:</i> Reads aloud simple sentences Finds key words and phrases from a text <i>Writing:</i> Writes words and sentences and paragraphs dictated with correct spellings, proper punctuation marks Learns to write words and sentences neatly on a line with proper spacing and punctuation Writes answers to questions based on the text Writes simple guided compositions Writes informal chits [notes], thank-you notes and invitations	<i>Reading and writing:</i> Reading textual material and writing answers based on the text Writing essays based on the text Reading literary stories and prose lessons Reading simple passages of reflective prose Reading and interpreting common instructions such as railway timetables Reading and interpreting maps, labels Reading short plays/passages/writing summaries

students are expected to demonstrate in the fifth and seventh grades respectively, and the generally low levels of English literacy skills expected from VM students.

Given our globalizing world, inequities relating to who has access to English and how access to it opens other communal doors—such as jobs and interviews—this plays itself out in differentiated ways. Larger cultural stratifications of caste and class seem to fall directly into this VM–EM chasm.

Shifts in Language Policies to Accommodate Globalizing Surges

There has, though, in recent years been increasing debate about changing English language policies in the VM towards preparing students from this medium to be more competitive in the global market. Certainly, the hiring of VM students in call center jobs has enhanced debate about spoken English skills. Would the standards of “good English” be held up by the local EM teachers? Or would they be set by native speakers? When do VM students seeking to acquire English set their own language proficiency standards?

These questions are hard to address but crucial for us all to consider for a number of reasons. For one, they contest our current disciplinary fears and discourses about hegemonic

cultural globalization, and nudge us into realms where we see Englishes used and contested, understood and not, amid diverse experiences. Be they in call centers, or Japanese hip-hop, they are a part of a cacophony of voices, bouncing off a range of spatial practices in all kinds of businesses, labor, leisure, politics, and cultural events. For another, they make us realize that we are at a crossroads in the discipline now where our current standards for judging language proficiency may be becoming defunct and where Englishes and their utter heterogeneity is openly acknowledged and celebrated.

Native Speaker

ALAN DAVIES

When we say:

I am a native speaker, or
s/he is a native speaker, or
you'll have to ask a native speaker, or
don't ask me, I'm not a native speaker,

what is it we are appealing to? What is it that human native speakers know? What sort of knowledge does the native speaker have? The answer is ambiguous: on the one hand there is the knowledge that an individual has of his/her own linguistic system. In the author's case that is the knowledge the author has of his own grammar, which we may call Grammar 1, the underlying rules employed in performance (Davies, 2003). Now if this author has his own grammar, so does everyone else: each one of us appeals to different rules, slightly different, of course, among members of a family, larger for English, when we consider the English of England, of Scotland, of the USA, and so on. This we may call Grammar 2: this is what Saussure termed *langue*. It is what enables members of a speech community to understand one another. But there is a third grammar, Grammar 3: this is the grammar of the human faculty of language, which is what all speakers share whether or not they share the same language. Grammar 3 underlies all language use, it is competence at its most abstract level; it is what has been called universal grammar or UG.

The problem with the Grammar 2 pursuit is that individual speakers of English (and of all other languages) disagree with one another as to what the grammar is. That has to be so if, as suggested, everyone has his/her own Grammar 1. The question for Grammar 2 is the boundary question: where does Grammar 2 of English end and Grammar 2 of, say, German begin? The boundary is, it seems, partly sociolinguistic and partly linguistic. There must be some connection between Grammar 1 and Grammar 2 which involves a level of abstraction linking an individual to other individuals who share membership with him/her in a speech community.

To be a native speaker linguistically, then, means operating a Grammar 2, an operation which allows for access to and intelligibility with other operators of the same Grammar 2. In his construct of language, Saussure similarly links the social to the linguistic, thereby providing an explanation for the existence of Grammar 2. Grammar 2 linguistics thus seems predicated on some kind of sociolinguistic interpretation of social life; while Grammar 1 and even more Grammar 3 are predicated on a psycholinguistic view.

Grammar 2 is of little interest in linguistics. Indeed, Chomsky and Peregrin Otero (2004) take the Grammar 1 position, arguing that there are no homogeneous speech communities and that the native speaker is an idealization while Ferguson (1983, p. vii) advised linguists to abandon the whole mystique of native speaker and mother tongue.

But there are challenges to the native speaker. One of the strongest is that of Thomas Paikeday (1985) who insisted that the native speaker is dead. Three such challenges are now considered.

The first challenge to the native speaker as the universal model comes from postcolonial World Englishes. Whatever else they are about, native speaker questions are about identity. Who is a native speaker? What is it one is a native speaker of? These are not far from the

“who am I?” question. In the 1940s and 1950s, Aimé Césaire and his fellow Francophone negritude writers were anguished at the loss of what they saw as their Black identity. Paradoxically, their anger was directed not at the French language but at their loss of something more profound—themselves. They were all *évolués*, *civilisés*, they had become French. But coexisting with their acceptance of Frenchness there was a profound regret at losing their negritude.

The early Anglophone African writers were skeptical. Identity was not at risk by writing in English because the English they spoke was a new variety, something not available in French to Francophone writers. Later, losing seems to have become more poignant, more salient, as we see in the progress of James Ngugi (Ngugi w’a Thiongo) who decided in mid-career to switch from writing in English to writing in Gikuyu, his mother tongue.

Graddol (1999, p. 68) writes of the “decline of the native speaker” and asks the “tantalising question . . . large numbers of people will learn English as a Foreign language in the 21st century . . . But will they continue to look towards the native speaker for authoritative norms of usage?” We might ask ourselves just how far such a question is peculiar to English. Would the same question be asked about, say, Welsh, Basque, Menonimi, Gikuyu? It does seem that English is something of a special case, a special postcolonial case.

Just as the Australian native speaker of English no longer takes account of the norms in British English, similarly the new variety of English native user (say of Singapore English) no longer takes account of these norms. How far the norms differ is an empirical question but it seems likely that as far as the written language is concerned, the differences are minimal. We may, therefore, aver that on linguistic grounds Singapore English does not exist but nor of course does British English. What does exist is the individual speaker. If a speaker identifies him/herself as a native speaker of Singapore English, then that is a sociolinguistic decision, which means that it is a decision about identity.

The second challenge to the native speaker comes from English as a lingua franca (ELF), the variety used by non-native speakers of English to interact with one another in business, professionally and so on (Seidlhofer, 2004). Although the term native user does not appear in the ELF literature, it seems reasonable to use it to refer to those proficient in ELF.

The ELF assertion is that English is increasingly being used as a vehicular language among interlocutors who do not speak one another’s language. In fact such speakers vastly outnumber native-speaker (NS) users (Graddol, 1999). What is claimed for ELF is that it is not metropolitan English (British, American, Australian, etc.). The claim, supported by corpora such as the Vienna–Oxford International Corpus of English, is that this ELF is a new international variety.

In general what these studies appear to show is a greater tolerance among ELF speakers—they are less focused on form, more concerned with reaching for the message. Seidlhofer argues that what matters is intelligibility rather than correctness. Thus, misunderstandings are resolved by communication strategies, interference from L1 interactional norms is rare. Overall, ELF talk seems to be “overtly consensus-oriented, cooperative and mutually supportive, and thus fairly robust” (Seidlhofer, 2004, p. 6).

The cognitive basis of much second language acquisition research distinguishes it from applied linguistics on concepts such as the native speaker. The applied linguistics view concerns the attainable performance of native speakers in contrast to non-native speakers while for second language acquisition research (SLAR) there is a fundamental difference between the native and the non-native speaker, marked by their different knowledge representations. Preston is clear about the centrality of the native speaker concept to SLAR: “From a psycholinguistic point of view, nativeness is almost the entire question of SLA.” Central though the concept may be, SLAR has been slow to take a critical view, to problematize the concept: “it is one of the least investigated (and for that matter, least understood) concepts in the field” (Han, 2004, p. 166). The long critical review by Han

2004 of the two volumes by Davies (1991, 2003) is therefore to be welcomed. As Han points out, SLAR has typically taken the native speaker for granted, ignoring the wild variation among native speakers. The goal of L2 teaching, argues Han, should “not be to create native speakers but rather L2 users” (Han, 2004, p. 184). But, she continues, “how do we define successful L2 users?”

The third challenge is ideological. In international language proficiency tests there are two important questions:

1. Whose norms are to be imposed in the test materials?
2. What are the consequences for test takers if the norm imposed by the test is not the “normal” variety accepted in their own society?

Concerned about these issues, Lowenberg (1993) carried out an analysis of the Test of English for International Communication, concluding that some items were biased against non-native speakers of English, particularly those in postcolonial settings.

One way of using the global norms to which Jenkins (2007) and Lowenberg (1993) object is to investigate to what extent local norms are appropriate both locally and beyond the local and to use this information in test development. Such an investigation is reported by Brown and Lumley (1998) referring to the development of an English proficiency test for Indonesian teachers of English. In spite of successful completion and fulfilling of the project’s aims, there was no take-up in Indonesia; it seemed that a local model was unacceptable to Indonesian teachers of English.

Further research on related lines (Hamp-Lyons & Davies, 2008; Zhang & Elder, 2011) compared the judgments by native and non-native speaking raters of speaking and writing performances by advanced learners of English. In all cases, the null hypothesis of there being no significant difference was upheld. There was no gulf between educated native and non-native speaking raters: they made similar judgments.

Escudero and Sharwood-Smith (2001) have argued that second language acquisition research should take a more critical view of the native speaker concept and have proposed the use of prototype theory which was developed by Eleanor Rosch. By using prototype theory, the native speaker becomes a gradient term, offering researchers greater precision in their investigations.

In her use of magnitude estimation, Sorace (2003) takes a different approach, describing non-native speakers in terms of their judgments of grammatical acceptability. Her results, confirmed across a number of languages, confirm that even native-like learners are categorically distinct from native speakers (but see Birdsong, 2004). What Sorace does not acknowledge is the range of linguistic ability among native speakers, of whom her educated native speaker informants may not be representative.

The differing positions of the psycholinguistic and the sociolinguistic appear to be irreconcilable. For the psycholinguist, no test is ever sufficient to demonstrate conclusively that native speakers (NSs) and non-native speakers (NNSs) are distinct: once NNSs have been shown to perform as well as NSs on a test the cry goes up for yet another test (Hyltenstam & Abrahamsson, 2000). For the sociolinguist there is always another (more) exceptional learner who will, when found, demonstrate that (exceptional) NNSs can be equated to NSs in terms of language knowledge and performance. The problem is that we cannot distinguish NNSs from NSs except by biography. So Cook (1999) is right to make a strong case for the NS–NNS distinction being one above all of biography. However, making the cut by biography solves only some problems and hides away the exceptions, the bilinguals, the movers away, the disabled intellectually, the exceptional learners. The fact is that mother tongue is not gender, it is not a given from the womb. It is, classically, social, just as culture is.

4 NATIVE SPEAKER

It may be that we cannot distinguish native speakers and non-native speakers because our premises are inherently flawed, as Hyltenstam and Abrahamsson (2000) point out, since there are different views of what being a native speaker means. They include:

1. native speaker by birth (that is by early childhood exposure),
2. native speaker by virtue of being a native user,
3. native speaker (or native speaker-like) by being an exceptional learner,
4. native speaker through education in the target language medium,
5. native speaker through long residence in the adopted country.

What is at issue is whether claiming to be a native speaker, to “own” the language, requires early childhood exposure. This argument focuses on the critical-period hypothesis, which remains hugely contentious. Most SLA researchers appear to agree that there is a critical period (CP) but disagree on (a) how absolute it is and (b) whether there are critical periods rather than just one critical period. Consensus seems to be for critical periods (Singleton, 2005). Stowe and Sabourin (2005) report that there is no support from brain imaging for changes in the child to adult brain, which puts a question mark against the CP itself. Birdsong, who seems fairly relaxed about the CP hypothesis, takes a more lateral position, querying not whether the non- or near-native can be or become a native speaker but just what it is the native speaker is capable of. That challenges the confident assertions of Hyltenstam and Abrahamsson about native-like levels. Just what are these native-like levels—are we talking all natives, some natives, or an ideal native?

The native speaker can be characterized in (at least) these six ways:

0. The native speaker acquires the L1 of which s/he is a native speaker in early childhood.
1. The native speaker has intuitions (in terms of acceptability and productiveness) about his/her idiolectal grammar.
2. The native speaker has intuitions about those features of the standard language grammar which are distinct from his/her own idiolectal grammar.
3. The native speaker has a unique capacity to produce fluent spontaneous discourse, which exhibits pauses mainly at clause boundaries (the “one clause at a time” facility) and which is facilitated by a large memory stock of complete lexical items.
4. The native speaker has a unique capacity to write creatively (and this includes literature at all levels from jokes to epics, metaphor to novels).
5. The native speaker has a unique capacity to interpret and translate into the L1 of which s/he is a native speaker (Davies, 2003).

All except (1) are contingent issues. In that way, the question “can a second language learner become a native speaker of a target language?” reduces to: “is it necessary to acquire a code in early childhood in order to become a native speaker of that code?” The answer to that question is a further question: what is it that the child acquires in acquiring his/her L1? The answer is items 2–5 above. The native user, then, can do everything a native speaker can do. However, given the lack of background culture and the amount of practice required, the task is so great that it is not likely that many second language learners become native speakers of their target language.

Brutt-Griffler (2002) agrees that the idealization of the NS is really a stand-in for the idealization of the standard language, itself the goal of education for both L1 and L2. And so the standard language is not the taken-for-granted production of the NS but the target language of the NS. What this recognizes is that the NS, just like the NNS, has the same target, the standard language.

Real native speakers and real native users are multidialectal and often multilingual, they live and breathe hybridity. The model for our norms and for our experiments is an idealized native speaker, what Brutt-Griffler calls the stand-in for the idealization of the standard language.

Not all languages enjoy their own standard variety. Not all have the variety of native speakers that world languages such as English and French have. Minority languages may have no standard language, they may have few native speakers. There may be more native users than native speakers—which seems the case of Irish Gaelic. Doerr and Kumagai (2009) propose encouraging learners “how to meaningfully and successfully communicate not only with ‘native speakers’ but also with various groups of ‘non-native speakers’ through being active participants in particular ‘communities of practice’” (Doerr & Kumagai, 2009, p. 315). This is not very far from the position of Jenkins (2007) on English as a lingua franca. Learners do indeed need goals, and the more modest one of the non-native speaker may be helpful; but they also need a model and it is uncertain what that might be unless it is the (idealized) native speaker.

There are native speakers and there is “the native speaker.” The first is all of us, the second an idealization. We are all native speakers of one or other code, language, idiolect. Some of us are educated, some not, some literate, some not, some creative orators, some not, and so on. The idea that all these native speakers are at C2, the highest level on the Council of Europe’s framework for reference scale makes no sense. Some perhaps are, but they are unusual. C2 is the level of “the native speaker,” an idealization (isomorphic with the standard language, itself an idealization). Models, scales, examinations which use as criterion the native speaker do not mean any or all native speakers. What they mean is “the (idealized) native speaker.” It is not surprising therefore when a group of educated non-native speakers out-performs a group of native speakers on a proficiency test. What their education has done for the non-native speakers is to imbue them with the knowledge of “the (idealized) native speaker,” that is of the standard language. Proficiency tests are all about knowledge of the standard language, which is exactly what non-native speakers have been trained in.

Nativism

ALAN DAVIES

Definitions

Webster (1913) defines nativism, from Latin *nativus* = inborn, natural, with two senses:

1. the disposition to favor the native inhabitants of a country in preference to immigrants from foreign countries
2. the doctrine of innate ideas, or that the mind possesses forms of thought independent of sensation.

Political Nativism

The first sense has seen long service in the USA (Michaels, 1995; Higham, 1988) as frequent waves of immigrants were made to feel unwelcome by those (often themselves recent immigrants) who regarded only themselves as truly native. This rejectionist attitude has, often enough, sought formal establishment in legal measures which, perhaps not openly, discriminate against new arrivals, who are blamed for society's ills. The sense of ownership by the oldcomers has obvious links with the term "native speaker" (Davies, 2003), which lays claim to a unique position in relation to a language. And although the two definitions from Webster quoted above seem distinct, there is a relationship, since both refer to ownership—ownership in the first case of land and culture and in the second of innate capacities. Both are possessed, as it were, of right; they are given by birth, by belonging to a group (in the first sense) and to humanity (in the second). Favoring the native inhabitants, that is those there earlier, has found expression in secret societies opposed to the Other (for example the Ku Klux Klan), in incarceration of "enemy aliens" such as Japanese Americans in the early years of World War II and in a long history of restrictive immigration measures such as the infamous "dictation test" of the White Australia policy (Davies, 1997; McNamara & Roever, 2006), to current legal barriers including language tests in Western Europe, Australia and New Zealand, and the USA.

Rationalism and Empiricism

It is the second sense of nativism that is the main topic of this entry: "the doctrine of innate ideas, or that the mind possesses forms of thought independent of sensation" (Webster, 1913).

This is a philosophical and psychological theory: it states that certain abilities (or capacities or mechanisms) are present in the child at birth. This is in contrast to empiricism, the blank slate (or *tabula rasa*) position of, for example, John Locke (1690) who wrote: "How comes (the mind) to be furnished? . . . Whence has it all the materials of reason and knowledge? To this I answer, in one word, from *experience*." Empiricism acknowledges that the child is born with certain capacities which allow it to learn from its environment, but those capacities have no content and are not specific to any kind of learning.

DOI: 10.1002/9781405198431.wbeal0856

The philosophical debate between nativism (also known as rationalism) and empiricism—between nature and nurture—is old. Famous nativists include Socrates, Plato, Kant, Descartes, and Pascal from Port Royal, while well-known empiricists include Aristotle, Hume, Berkeley, J. S. Mill, and C. S. Peirce. The extension of the nativist theory from psychology to linguistics is not surprising, given that language can be regarded as a psychological ability: those most influential on linguistic nativism, such as Chomsky (1980), Fodor (1998) and Pinker (1994), are themselves as much interested in cognition as in language. The argument here is that children are born with certain psychological capacities that enable them to learn and acquire skills such as language. For the empiricist, nothing is passed on at birth: all is there in the context to be discovered and built on. For the nativist this cannot be since what the young child has to do is to learn a very complicated grammar, so complicated, according to Chomsky (1965) that the child must have an innate language-learning model, a language acquisition device (LAD). How is it, asks Chomsky, that children are fully capable of uttering and responding to sentences they have never heard? This is the “poverty of the stimulus” argument: children acquiring their first language (L1) are exposed to a finite set of linguistic stimuli but are expected to cope with an infinite set, that is with new sentences they have never heard before. They must, so the argument goes, get help from somewhere, help which has not been available during their acquisition period. Hence the fall-back of nativism.

But this approach has been challenged on the grounds that children do have available to them such features as generalization and statistical learning. Complexity theory and game theory have recognized that complicated systems can be deciphered by apparently naïve agents (McDonald & Ramscar, 2001; Yarlett, 2008).

Attempts to reconcile strict nativism and some version of empiricism can be found in the discussion by Cowie (1999) of enlightened empiricism and by Karmiloff-Smith (1996). Karmiloff-Smith has put forward what she labels representational re-description, which moderates strict nativism through the brain becoming modular in certain domains rather than the nativist position of modules being innate.

Universal Grammar

Nativism presupposes universals. Linguistic nativism took as its bedrock universal grammar (UG), a theory of linguistics which assumes principles of grammar common to all languages. Language acquisition both for L1 and L2 is a main source of data, descriptive rather than experimental, but the explanations have to be at a highly abstract level of linguistic universals, since they need to be common to all languages in order to demonstrate their universality. Thus “If X holds true, then Y occurs”, for example: If a language is head neutral (for example English) it will have prepositional phrases; if and only if it is head final (for example Japanese) will it have postpositional phrases.

The idea is not new and can be found in the work of the 13th-century scholar Roger Bacon, who maintained that there is a common grammar to all languages. For Chomsky (1965, 1980) the clincher is that children learn in spite of negative evidence, since by definition speakers do not use expressions which violate restrictions on the language. Here again, the child acquires the language on partial evidence. UG offers a solution by making certain restrictions universal characteristics of human language. These characteristics are accessed by means of an innate language faculty module (the language acquisition device). Creole languages (Bickerton, 1981) are said to support UG, for example by their common default point of reference to past time, while questions are expressed only by intonation. But Hudson-Kam and Newport (2009) argue that acquisition can take place by means of children’s facility in systematizing the language they hear, based on probability and frequency of forms.

UG is not without its critics: Sampson, Roediger, Elman, and Hurford comment on its basic premises, even suggesting that the concept is “fundamentally confused” (Griffiths, 2002). Such criticisms point to what one might call the enlightened empiricism approach by offering agency to the acquirer who is creative and perceptive and not a dummy. And Chomsky himself has backtracked somewhat to a so-called minimalist program, which seems to assert nativism without the need for UG (Chomsky, 1993).

Other features of nativism include the appeal to linguistic universals (properties possessed by all possible natural languages) although it is disputed that such universals—which are not themselves disputed—necessitate nativism (Tomasello, 2003). There is also the sensitive or critical period argument—that language learning (like other developmental learning) diminishes after the onset of puberty: again, this is disputed because of the dearth of evidence for acquisition of an L1. It is surprising that little evidence is presented for the sensitive period with regard to the learning of a second language: there are exceptions, for example Lydia White who has worked on UG with regard to second language acquisition (White, 2003).

The linguistic nativist follows the rationalist position, which regards reason as the main source of knowledge. This is taken to mean that there are innate principles, in logic, in math, in ethics, and perhaps too in aesthetics, which all are born with. These are high-level principles which need to be embodied by encounters with the substance of logic, math, and so on. The linguistic nativist would add the language principle, which is universally implanted, realizing itself in the experience the child normally has with the language of caretakers and peers.

As with physical development, the language faculty lies dormant until the appropriate conditions trigger it into action. The argument with empiricism is in part about the role of perception. For empiricists, knowledge (and in our case language) must be tested by sense experience, that is by perception. For rationalists, reason alone provides for the acquisition of knowledge. And there lies the dilemma and the source of the disagreement between Chomsky and Piaget. Piaget’s theory is neo-behaviorist: the child’s incremental learning is based on probability judgments derived from previous experience of similar situations. For the rationalist, this is anathema.

Chomsky and Piaget disagree over the issue of hypothesis testing: for Chomsky, this is crucial and it assumes both a language acquisition device and the presence of UG. For Piaget (1985), hypothesis testing is not necessary: instead, he favors the process of disequilibrium. This allows him to describe both learning and development, while nativists, he maintains, can describe only learning.

The rationalist takes as axiomatic the innateness of certain capacities. Chomsky’s argument is that otherwise a language would be just too difficult to learn so expertly.

Language learning is not really something that the child does; it is something that happens to the child placed in an appropriate environment, much as the child’s body grows and matures in a predetermined way when provided with appropriate nutrition and environmental stimulation. (Chomsky, 1993, p. 519)

And so, the nativist typically makes the following assumptions about language acquisition.

1. Language acquisition is rapid.
2. Language acquisition is instantaneous.
3. Language acquisition happens without direct instruction.
4. Language acquisition happens in spite of inadequate output.

Each of these assumptions can be challenged.

4 NATIVISM

1. Acquisition is not rapid: it takes children five years to become intelligible to strangers.
2. Acquisition is not instantaneous (if it were, why do we need five years to reach intelligibility?) Children constantly make errors along the way.
3. (Direct) instruction does take place: rather than replying to a child's error by saying "Don't say that!" parents and other caregivers constantly reformulate and model correct forms.
4. Is input inadequate? This is a moot point—the poverty of the stimulus position has its weaknesses since it is not clear just what the child really does lack in terms of linguistic stimuli (Chouniard & Clark, 2003).

These are strong challenges, supporting the view that what is innate is not a language faculty, but mechanisms which provide the capacity for language acquisition and learning.

Linguistic Nativism or General Nativism?

So far I have assumed that there is just one view of linguistic nativism. As Scholz and Pullum point out, that is just not so: "Different versions of linguistic nativism will have different forms of general nativism as plausible competitors" (2002, p. 222). And by general nativism what they mean is that there is innateness, but none of it is specifically linguistic.

There appear, then, to be three possible positions with regard to linguistic innateness:

1. the strong linguistic nativism position (plus UG),
2. the weak linguistic nativism position (with specific language acquisition capacities but with no UG), and
3. general nativism (with general learning mechanisms which apply to language as well as to other domains).

Chomsky is, or perhaps was—he appears to have backtracked somewhat in recent years—a leading exponent of position (1). Position (2) is well supported by O'Grady (2003), who argues that position (1) requires the inclusion within linguistic nativeness of UG. He prefers the non-UG alternative, that is position (2). But O'Grady seems also to lean toward the third position, the position of general nativism, which he associates with connectionism:

Recent work in connectionism denies the existence of conventional syntactic representation of UG and of an inborn acquisition device specifically for language. Language acquisition, it is claimed, is not fundamentally different from any other type of learning and can be accounted for by the same mechanisms as are required for interaction with the environment in general. (O'Grady, 2003, p. 57)

O'Grady himself is not an advocate of the connectionist position. He favors "general (or cognitive) nativism," which posits "the existence of hierarchically structured symbolic representations" (2003, pp. 57–8), very much the general nativist position.

Unusually for nativism researchers, O'Grady is prepared to extend the field for investigation to second language acquisition. He writes:

There is surely a place for the study of second language acquisition in all of this. At the very least, research on second language learning provides opportunities to observe the acquisition device functioning under conditions of duress—either because of extreme limitations on the available input (as in the case of classroom language) or because one or more of its component modules has been compromised. (O'Grady, 2003, p. 58)

Geoffrey Sampson (2005) is a fierce exponent of the empiricist position, insisting that his data of modern spoken English show “how unrealistic the nativists’ beliefs about language behaviors are.”

His more sober criticism is that UG theories are not falsifiable—the rules that nativists put forward are just observations about existing languages and not predictions about what might be (Sampson, 2005). This is precisely the point. Nativists have to fall back on what amounts to a belief, while empiricists cannot sensibly be content with the extreme *tabula rasa* position. If children had no tendencies, capacities, mechanisms they would surely never learn anything—they would not develop.

It does seem that some coming together of general nativism and an enlightened empiricism is the sensible compromise. Innateness (or nativism) is not a coherent theory. Bateson (2000) and Griffiths (2002) have suggested that it is “fundamentally flawed.” Attempts to save a pure nativism through the proposal of canalization (Waddington, 1990) or psychological primitiveness (Cowie, 1999; Sampson, 2002) are not obviously helpful: for language acquisition, the first seems to trivialize the debate and the second to give up explanation in despair. Common sense indicates that humans are born with certain capacities, mental as well as physical. Those capacities enable them to respond to their environment. Whether those capacities indicate a specifically linguistic device is unclear and may not be important.

Nativism and nativeness both preserve the idea of passivity: nativism’s innate ideas and the defining of nativeness on the grounds of birth or origin. Both terms derive through Old French from “native,” the cognate of which is naïf, meaning natural with the sense of not being able to help one’s birth or one’s origins.

Nativeness is defined as the quality of belonging to or being connected with a certain place or region by virtue of birth or origin. Hence “native speaker,” one who has a special relation to a language through birth or origin and so may lay claim to ownership of that language. Nativism is defined as the doctrine of innate ideas or that the mind possesses forms of thought independent of sensation. The term nativism derives from nature, meaning inborn or natural, hence the claim that one is born with innate ideas (specifically for language with a language faculty) which are there by nature.

As this entry has suggested, a strong form of nativism is difficult to uphold. In the same way, nativeness’s basic premise of birth or origin can be queried: nativeness for people (if not for plants) can be multiple (in mixed communities) or subtractive (by moving to another origin). And the rise of the near-native speaker or native user challenges the claim of language ownership by the native speaker.

This study by Clark & Lappin (2011) provides evidence for the poverty of the stimulus theory in its examination of several different theoretical approaches to the formal learnability of the class of natural languages.

Nativeness and Language Pedagogy

VIVIAN COOK

A native speaker is typically defined as “a person who has spoken a certain language since early childhood” (McArthur, 1992, p. 682). Extended lists of specific attributes of nativeness are discussed by Davies (1996), Johnson and Johnson (1998), and Stern (1983) and include subconscious knowledge of rules, identification with a language community, and ability to produce fluent discourse, most of which seem a matter of degree rather than defining characteristics (Cook, 1999)—some native speakers are as dysfluent as any non-native, for instance.

One difficulty with the concept of native speaker is finding one. Most languages have regional, class, and gender varieties spoken within one country, let alone those spoken in different countries. Should the target native speaker of English, say, hail from London or Glasgow, Boston or Chicago, Toronto or Brisbane? Normally a native speaker is taken to be someone speaking a standard “educated” form of the language. This brings in a strong element of idealization as the representative native speaker is chosen largely for reasons of social status; the Received Pronunciation (RP) form of English taken to be native British English is in fact spoken by a small minority. Using the native speaker as a model for second language acquisition (SLA) research and second language (L2) teaching is not unproblematic.

Most L2 learners and language teachers would nevertheless probably say that the goal of learning another language is to speak it like a native speaker. Yet many would admit that this goal is unattainable for all but a highly select few. Why then have SLA research and language teaching concentrated on a goal that is out of reach, indeed logically unachievable under the definition given above?

One explanation for the insistence on the native speaker is that it enables the in-group of native speakers to exert power over out-groups of non-natives. Linguists and the general public have become more sensitive to questions of linguistic power, whether gender, class, or race, but not to those of nativeness. In the 1990s a group of applied linguists including R. Phillipson (1992), A. Holliday (1994), and A. Pennycook (1994) drew attention to the political and economic issues of this. The native speakers and the nation they come from claim the privilege of being the only rightful owners of their language and so maintain their power and influence over all the rest.

SLA research for forty years has ostensibly been working within the interlanguage paradigm that learners have an independent language system of their own, related to the target L2 but not identical with it, and constructed by many processes. Yet time and again research measures the L2 learner against the native speaker: Their peak of achievement is seen as “absolute native-like command of an L2” (Hyltenstam & Abrahamsson, 2003, p. 575). SLA research methodology too has depended heavily on measuring L2 users against native speakers (Cook, 1997), L2 grammaticality judgments being assessed against those of native speakers, obligatory occurrences of grammatical items being defined as those that natives would use in that context, and L2 access to universal grammar (UG) being seen as a matter of whether L2 users can have the same grammars as native speakers. The native speaker has been the omnipresent ghost in the machine.

Language teaching has taken a similar path. Most specifications of the target for the student learner embodied in syllabuses and examinations implicitly accept the native-speaker goal. The Common European Framework (Council of Europe, 2001, p. 6), for instance, talks inter alia about L2 learners having “regular interaction with native speakers,” encountering language “delivered at fast native speed,” and being able to “sustain relationships with native speakers without unintentionally amusing or irritating them,” with little mention of their dealings with non-natives. One question for language teaching is then whether the monolingual native speaker is the proper target for students to aim at. Partly this is a question of fairness. Given the variety of native speakers, why should it be acceptable for your speech to show you come from Detroit or Newcastle upon Tyne but not from Paris or Tokyo? Why should only a native speaker have the privilege of proclaiming their identity as a person from a particular place? Some national syllabuses do now have targets other than the emulation of native speaker, such as the Japanese goal of “Japanese with English Abilities.”

There is also the practical issue for English and other hypercentral and supercentral languages that most L2 communication is between fellow non-native speakers and does not involve native speakers, whether, say, Japanese businessmen talking to Arabic businessmen in English, or pilots using English everywhere in the world for talking to ground control; 74% of tourist encounters in English do not involve native speakers. Incidentally, native speakers are actually worse than non-native speakers in some specialized areas such as aviation English (Alderson, 2009). The primary target for much language teaching may be using the L2 effectively to other L2 users, and communicating with native speakers is a secondary target. Hence researchers have been gathering information about L2 user speech under the banner of “English as lingua franca” (Jenkins, 2000; Seidlhofer, 2004).

A corollary of the native-speaker target is the belief that native speakers make the best language teachers; if native speakers are the only true speakers of a language, clearly a non-native-speaker teacher is a second-rate substitute. UK universities, for example, tend to employ native speakers as language teachers, whether the language is Spanish, Japanese, or Russian; advertisements for language schools emphasize that the teachers are natives everywhere in the world. But if the target is to be a successful L2 user rather than an imitation native speaker, the non-native-speaker teacher is clearly a better model and is someone who has acquired the L2 by the same route as the students.

Natural Language Processing and Language Learning

DETMAR MEURERS

As a relatively young field of research and development that began with work on cryptanalysis and machine translation around 50 years ago, natural language processing (NLP) is concerned with the automated processing of human language. It addresses the analysis and generation of written and spoken language, though speech processing is often regarded as a separate subfield. NLP emphasizes processing and applications, and as such can be seen as the applied side of computational linguistics, the interdisciplinary field of research concerned with formal analysis and modeling of language and its applications at the intersection of linguistics, computer science, and psychology. In terms of the language aspects dealt with in NLP, traditionally lexical, morphological and syntactic aspects of language were at the center of attention, but aspects of meaning, discourse, and the relation to the extralinguistic context have become increasingly prominent in the last decade. A good introduction and overview of the field is provided in Jurafsky and Martin (2009).

This entry explores the relevance and uses of NLP in the context of language learning, focusing on written language. As a concise characterization of this emergent subfield, the discussion will focus on motivating the relevance, characterizing the techniques, and delineating the uses of NLP; more historical background and discussion can be found in Nerbonne (2003) and Heift and Schulze (2007).

One can distinguish two broad uses of NLP in this context: on the one hand, NLP can be used to analyze *learner language*, i.e., words, sentences, or texts produced by language learners. This includes the development of NLP techniques for the analysis of learner language by tutoring systems in intelligent computer-assisted language learning (ICALL), automated scoring in language testing, as well as the analysis and annotation of learner corpora.

On the other hand, NLP for the analysis of *native language* can also play an important role in the language-learning context. Applications in this second domain support the search for and the enhanced presentation of native-language reading material for language learners, provide targeted access to relevant examples from native-language corpora, or support the generation of exercises, games, and tests based on native-language materials.

NLP and the Analysis of Learner Language

Intelligent language tutoring systems (ILTS) use NLP to provide individualized feedback to learners working on activities, usually in the form of workbook-style exercises as in e-Tutor (Heift, 2010), Robo-Sensei (Nagata, 2009), and TAGARELA (Amaral & Meurers, 2011). The NLP analysis may also be used to individually adjust the sequencing of the material and to update the learner model. Typically, the focus of the analysis is on form errors made by the learner, even though, in principle, feedback can also highlight correctly used forms or target aspects of meaning or the appropriateness of a learner response given the prompt and input provided by an exercise.

What Motivates the Use of NLP in a Tutoring System?

To be able to provide feedback and keep track of abilities in a learner model, an ILTS must obtain information about the student's abilities. How this is done depends directly on the nature of the activity and the type of learner responses the program supports, i.e., the ways in which it requires the learner to produce language or interact with the system. The interaction between the input given to a learner to carry out a task and the learner response is an important topic in language assessment (see Bachman & Palmer, 1996) and arguably this is equally crucial for determining the system-analysis requirements for different activity types in the ILTS context.

For exercises which explicitly or implicitly require the learner to provide responses using forms from a small, predefined set, it is often possible to anticipate all potential well-formed and ill-formed learner responses, or at least the most common ones given a particular learner population. The intended system feedback for each case can then be explicitly specified for each potential response. In such a setup, knowledge about language and learners is exclusively expressed in this extensional mapping provided offline when the exercise is created. Sometimes, targets are allowed to include regular expressions (http://en.wikipedia.org/wiki/Regular_expression) to support a more compact specification. The online process of comparing an actual learner response to the anticipated targets is a simple string comparison requiring no linguistic knowledge and thus no NLP. Correspondingly, the quiz options of general course management systems (Moodle, ILIAS, etc.) can support such language exercises just as they support quizzes for math, geography, or other subjects. The same is true of the general tools underlying the many quiz pages on the Web (e.g., <http://www.eslcafe.com/quiz/>). Tools such as Hot Potatoes (<http://hotpot.uvic.ca/>) make it easier to specify some exercise forms commonly used in language teaching, but also use the same general processing setup without NLP.

For many types of language-learning activities, however, extensionally specifying a direct and complete mapping between potential learner input and intended feedback is not feasible. Nagata (2009, pp. 563–4) provides a clear illustration of this with an exercise taken from her Japanese tutor Robo-Sensei, in which the learner reads a short communicative context and is asked to produce a sentence in Japanese that is provided in English by the system. The learner response in this exercise is directly dependent on the input provided by the exercise (a direct response in the terminology of Bachman & Palmer, 1996), so that a short, seven-word sentence can be defined as the target answer. Yet after considering possible well-formed lexical, orthographical, and word-order variants, one already obtains 6048 correct sentences which could be entered by the learner. Considering incorrect options, even if one restricts ill-formed patterns to incorrect particle and conjugation choices, one obtains almost a million sentences. Explicitly specifying a mapping between a million anticipated responses and their corresponding feedback clearly is infeasible. Note that the explosion of possible learner answers illustrated by Nagata already is a problem for the direct response in a constrained activity, where the meaning to be expressed is fixed and only form variation is anticipated. A further dimension of potential variation in responses arises when going beyond the analysis of language as a system (parallel to *system-referenced tests* in language assessment, see Baker, 1989) to an analysis of the ability to use language to appropriately complete a given task (*performance-referenced*).

In conclusion, for the wide range of language activities supporting significant well-formed or ill-formed variation of form, meaning, or task-appropriateness of learner responses, it is necessary to abstract away from the specific string entered by the learner to more general classes of properties by automatically analyzing the learner input using NLP algorithms and resources. Generation of feedback, learner-model updating, and instructional sequencing can then be based on the small number of language properties and categories derived through NLP analysis, instead of on the large number of string instances they denote.

What Is the Nature of the Learner Language Properties to Be Identified?

Research on intelligent language tutors has traditionally focused on learner errors, identifying and providing feedback on them. Automatic analysis can also be used in an ILTS to identify well-formed language properties in order to provide positive feedback or record in a learner model that a given response provided evidence for the correct realization of a particular construction, lexical usage, or syntactic relation. All approaches to detecting and diagnosing learner errors must explicitly or implicitly model the space of well-formed and ill-formed variation that is possible given a particular activity and a given learner. Insights into activity design and the language development of learners thus are crucial for effective NLP analysis of learner errors.

Errors are also present in native-language texts and the need to develop robust NLP which also works in suboptimal conditions (due to unknown or unexpected forms and patterns, noise) has been a driving force behind the shift from theory-driven, rule-based NLP of the 80s and 90s to the now-dominant data-driven, statistical, and machine-learning approaches. However, there is an important difference in the goal of the NLP use in an ILTS compared to that in other NLP domains. NLP is made robust to gloss over errors and unexpected aspects of the system input with the goal of producing some result, such as a syntactic analysis returned by a parser or a translation provided by a machine-translation system. The traditional goal of the NLP in an ILTS, on the other hand, is to identify the characteristics of learner language and the ways in which learner responses diverge from the expected targets in order to provide feedback to the learner. So errors here are the goal of the abstraction performed by the NLP, not something to be glossed over by robustness of processing.

Writers' aids such as the standard spell and grammar checkers (Dickinson, 2006) share the ILTS focus on identifying errors, but they rely on assumptions about typical errors made by native speakers which do not carry over to language learners. For example, Rimrott and Heift (2008, p. 73) observe that "in contrast to most misspellings by native writers, many L2 misspellings are multiple-edit errors and are thus not corrected by a spell checker designed for native writers." Tschichold (1999) also points out that traditional writers' aids are not necessarily helpful for language learners since learners need more scaffolding than a list of alternatives from which to choose. Writers' aids tools that target language learners, such as the ESL Assistant (Gamon et al., 2009), therefore provide more feedback and, for example, concordance views of alternatives to support the language learner in understanding the alternatives and choosing the right option. The goal of writers' aids is to support the second language user in writing a functional, well-formed text, not to support them in acquiring the language, as is the goal of an ILTS.

NLP methods for the diagnosis of learner errors fall into two general classes. On the one hand, most of the traditional development has gone into *language-licensing approaches*, which analyze the entire learner response; on the other hand, there is a growing number of *pattern-matching approaches*, which target specific error patterns and types (e.g., preposition or determiner errors), ignoring any learner response or part thereof that does not fit the pattern.

Language-Licensing Approaches

Language-licensing approaches are based on formal grammars of the language to be licensed, which can be expressed in one of two general ways (see Johnson, 1994). In a *validity-based* system, a grammar is a set of rules, and recognizing a string amounts to finding valid derivations. Simply put, the more rules are added to the grammar, the more types of strings can be licensed; if there are no rules, nothing can be licensed. In a *satisfiability-based* setup, a grammar is a set of constraints and a string is licensed if its

model satisfies all constraints in the grammar. Thus, the more constraints are added, the fewer types of strings are licensed; if there are no constraints in the grammar, any string is licensed.

Corresponding to these two types of formal grammars, there are essentially two types of approaches to analyzing a string with the goal of diagnosing learner errors. The *mal-rule approach* follows the validity-based perspective and uses standard parsing algorithms. Starting with a standard native-language grammar, rules are added to license strings which are used by language learners but not in the native language, i.e., so-called mal-rules used to license learner errors (see., e.g., Sleeman, 1982; Matthews, 1992, and references therein). Given that a specific error type can manifest itself in a large number of rules—for example, an error in subject–verb agreement can appear in all rules realizing subjects together with a finite verb—*meta-rules* can be used to capture generalizations over rules (Weischedel & Sondheimer, 1983). The mal-rule approach can work well when errors correspond to the local tree licensed by a single grammar rule. Otherwise, the interaction of multiple rules must be taken into account, which makes it significantly more difficult to identify an error and to control the interaction of mal-rules with regular rules. To reduce the search space resulting from rule interaction, the use of mal-rules can be limited. In the simple case, the mal-rules are only added after an analysis using the regular grammar fails. Yet this only reduces the search space for parsing well-formed strings; if parsing fails, the question of which mal-rules need to be added remains. The ICICLE system (Michaud & McCoy, 2004) presents an interesting solution by selecting the groups of rules to be used based on *learner modeling*. It parses using the native rule set for all structures of which the learner has shown mastery. For structures assumed to currently be acquired by the learner, both the native and the mal-rules are used. And for structures beyond the developmental level of the learner, neither regular nor mal-rules are included. When moving from traditional parsing to parsing with probabilistic grammars, one obtains a further option for distinguishing native from learner structures by inspecting the probabilities associated with the rules (see Wagner & Foster, 2009, and references therein).

The second group of language-licensing approaches is typically referred to as *constraint relaxation* (Kwasny & Sondheimer, 1981), which is an option in a satisfiability-based grammar setup or when using rule-based grammars with complex categories related through unification or other constraints which can be relaxed. The idea of constraint relaxation is to eliminate certain constraints from the grammar, for example, specifications ensuring agreement, thereby allowing the grammar to license more strings than before. This assumes that an error can be mapped to a particular constraint to be relaxed, i.e., the domain of the learner error and that of the constraint in the grammar must correspond closely. Instead of eliminating constraints outright, constraints can also be associated with weights controlling the likelihood of an analysis (Foth, Menzel, & Schröder, 2005), which raises the interesting issue of how such flexible control can be informed by the ranking of errors likely to occur for a particular learner given a particular task. Finally, some proposals combine constraint relaxation with aspects of mal-rules. Reuer (2003) combines a constraint relaxation technique with a standard parsing algorithm modified to license strings in which words have been inserted or omitted, an idea which essentially moves generalizations over rules in the spirit of meta-rules into the parsing algorithm.

Pattern Matching

For pattern matching, the most common approach is to match a typical *error pattern*, such as the pattern looking for “of cause” in place of “of course”. By performing the pattern matching on the part-of-speech tagged, chunked, and sentence-delimited learner string, one can also specify error patterns such as that of a singular noun immediately preceding

a plural finite verb (e.g., in *The baseball team are established*). This approach is commonly used in standard grammar checkers and, for example, realized in the open-source LanguageTool (Naber, 2003; <http://www.languagetool.org>), which was not developed with language learners in mind, but readily supports the specification of error patterns that are typical for particular learner populations.

Alternatively, pattern-matching can also be used to identify *context patterns* which are likely to include errors. For example, determiners are a well-known problem area for certain learners of English. Using a pattern which identifies all nouns (or all noun chunks) in the learner response, one can then make a prediction about the correct determiner to use for this noun in its context, and compare this prediction to the determiner use (or lack thereof) in the learner response. Given that determiners and preposition errors are among the most common English learner errors found, and that the task lends itself well to the current machine-learning approaches in computational linguistics and raises the interesting general question how much context and which linguistic generalizations are needed for predicting such functional elements, it is currently one of the most active areas of NLP research in the context of learner language (see, e.g., De Felice, 2008, and references therein).

Complementing the analysis of form, for an ILTS to offer meaning-based, contextualized activities it is important to provide an *automatic analysis of meaning aspects*, for example, to determine whether the answer given by the learner for a reading comprehension question makes sense given the reading. While most NLP work in ILTS has addressed form issues, some work has addressed the analysis of meaning in the context of ILTS (Delmonte, 2003; Ramsay & Mirzaiean, 2005; Bailey & Meurers, 2008) and the issue is directly related to work in computer-assisted assessment systems outside language learning, for example, for evaluating the answers of short-answer questions (see Pérez Marin, 2007, and references therein) or in essay scoring (see Attali & Burstein, 2006, and references therein). In terms of NLP methods, it also directly connects to the growing body of research on recognizing textual entailment and paraphrase recognition (Androutsopoulos & Malakasiotis, 2010).

Shifting the focus from the analysis techniques to the interpretation of the analysis, just as the activity type and the learner play an important role in defining the space of variation to be dealt with by the NLP, the interpretation and feedback provided to the learner needs to be informed by activity and learner modeling (Amaral & Meurers, 2008). While feedback in human–computer interaction cannot simply be equated with that in human–human interaction, the results presented by Petersen (2010) for a dialogue-based ILTS indicate that results from the significant body of research on the effectiveness of different types of feedback in instructed second language acquisition (SLA) can transfer across modes, providing fresh momentum for research on feedback in the CALL domain (e.g., Pujolà, 2001).

A final important issue arising from the use of NLP in ILTS concerns the resulting lack of teacher autonomy. Quixal, Preuß, Boullosa, & García-Narbona (2010) explore putting the teacher back in charge of designing their activities with the help of an *ICALL authoring system*—a complex undertaking since in contrast to regular CALL authoring software, NLP analysis of learner language needs to be integrated without presupposing any understanding of the capabilities and limits of the NLP.

Learner Corpora

While there seems to have been little interaction between ILTS and learner-corpus research, perhaps because ILTS research traditionally has focused on exercises whereas most learner corpora consist of essays, the analysis of learner language in the annotation of learner corpora (see Granger, 1998) can be seen as an offline version of the online analysis performed by an ILTS (Meurers, 2009).

What Motivates the Use of NLP for Learner Corpora?

In contrast to the automatic analysis of learner language in an ILTS providing feedback to the learner, the annotation of learner corpora essentially provides an index to learner language properties in support of the goal of advancing our understanding of acquisition in SLA research and to develop instructional methods and materials in foreign-language teaching (FLT). Corpus annotation can support a more direct mapping from theoretical research questions to corpus instances (Meurers, 2005), yet for a reliable mapping it is crucial for corpus annotation to provide only reliable distinctions which are replicably based on the evidence found in the corpus and its meta-information, for which clear measures are available (Artstein & Poesio, 2009).

What Is the Nature of the Learner Language Properties to Be Identified?

Just as for ILTS, much of the work on annotating learner corpora has traditionally focused on learner errors, for which a number of *error-annotation schemes* have been developed (see Díaz Negrillo & Fernández Domínguez, 2006, and references therein). There is so far no consensus, though, on the external and internal criteria, that is, which error distinctions are needed for which purpose and which distinctions can reliably be annotated based on the evidence in the corpus and any meta-information available about the learner and the activity which the language was produced for. An explicit and reliable error-annotation scheme and a gold-standard reference corpus exemplifying it is an important next step for the development of automatic error-annotation approaches, which need an agreed-upon gold standard for development as well as for testing and comparison of approaches. Automating the currently manual error-annotation process using NLP would support the annotation of significantly larger learner corpora and thus increase their usefulness for SLA research and FLT.

Since error-annotation results from the annotator's comparison of a learner response to hypotheses about what the learner was trying to say, Lüdeling, Walter, Kroymann, and Adolphs (2005) argue for making the target hypotheses explicit in the annotation. This also makes it possible to specify alternative error annotations for the same sentence based on different *target hypotheses* in multilevel corpus annotation. However, Fitzpatrick and Seegmiller (2004) report unsatisfactory levels of interannotator agreement in determining such target hypotheses. It is an open research issue to determine for which type of learner responses written by which type of learners for which type of tasks such target hypotheses can reliably be determined. Target hypotheses arguably should be limited to encoding only the minimal commitments necessary for error identification (or any other type of robust annotation, i.e., any annotation supporting variation in the realization of its classes); and in place of target hypothesis strings, they might have to be formulated at more abstract levels, for example, lemmas in topological fields, or sets of concepts the learner was trying to express. In either case, if the target hypotheses are made explicit, the second step from target hypothesis to error identification can be studied separately and is assumed to be realizable with high reliability.

Returning to the general question about the nature of the learner-language properties which are relevant, SLA research essentially observes correlations of linguistic properties, whether erroneous or not. And even research focusing on learner errors needs to identify correlations with linguistic properties, for example, to identify overuse/underuse of certain patterns, or measures of language development. While the use of NLP tools trained on native-language corpora is a useful starting point for providing a range of linguistic annotations, an important next step is to explore the creation of annotation schemes and methods capturing the *linguistic properties of learner language* (see Meunier, 1998; Dickinson & Ragheb, 2009; Díaz Negrillo, Meurers, Valera, & Wunsch, 2010, and references therein).

In terms of using NLP for providing *general measures of language development*, Laufer and Nation (1995) propose the use of lexical frequency profiles (LFPs) to measure the active vocabulary of learners, and a machine-learning approach for predicting the levels of essays written by second language learners based on a variety of word lists can be found in Pendar and Chapelle (2008). Beyond the lexical level, Lu (2009) shows how the revised D-Level Scale (Covington, He, Brown, Naçi, & Brown, 2006) encoding the order in which children acquire sentences of increasing complexity can be measured automatically. Related measures are used in the automated analysis of the complexity in second language writing (Lu, 2010). Finally, some learner-language-specific aspects can only be identified once other levels of linguistic analysis have been annotated. For example, Hawkins and Buttery (2009) identify so-called criterial features distinguishing different proficiency levels on the basis of part-of-speech tagged and parsed portions of the Cambridge Learner Corpus.

NLP and the Analysis of Native Language for Learners

The second domain in which NLP connects to language learning derives from the need to expose learners to authentic native language and its properties, and to give them opportunity to interact with it. This includes work on searching for and enhancing authentic texts to be read by learners as well as the automatic generation of activities and tests from such texts. In contrast to the ILTS side of ICALL research covered in the first part of this entry, the NLP in the applications under discussion here is used to process native language in authentic texts, hence it is referred to as ATICALL.

Most NLP research is developed and optimized for native-language material, and it is easier to obtain enough annotated language material to train the statistical models and machine-learning approaches used in current research and development, so that in principle a wide range of NLP tools with high-quality analysis is available—even though this does not preempt the question of which language properties are relevant for ATICALL applications and whether those properties can be derived from the ones targeted by standard NLP.

What Motivates the Use of NLP in ATICALL?

Compared to using prefabricated materials such as those presented in textbooks, NLP-enhanced searching for materials in resources such as large corpora or the Web makes it possible to provide on-demand, individualized access to up-to-date materials. It supports selecting and enhancing the presentation of texts depending on the background of a given learner, the specific contents of interest to them, and the language properties and forms of particular relevance given the sequencing of language materials appropriate for the learner's stage (see, e.g., Pienemann, 1998).

What Is the Nature of the Learner Language Properties to Be Identified?

Traditionally, the most prominent property used for selecting texts has been a general notion of readability, for which a number of readability measures have been developed (DuBay, 2004). While the traditional readability measures were computed by hand, the computation of most has since been automated. Most of the measures involve only simple surface properties such as counts of average word and sentence lengths, but sometimes also sophisticated NLP such as morphological analysis is needed (see Ott & Meurers, 2010, section 3.2). Work in the Coh-Metrix project emphasizes the importance of analyzing text cohesion and coherence and of taking a reader's cognitive aptitudes into account for making predictions about reading comprehension (McNamara, Louwerse, & Graesser, 2002).

Other recent approaches replace the readability formulas with more complex statistical classification methods for predicting the reading level of texts (see, e.g., Schwarm & Ostendorf, 2005; Collins-Thompson & Callan, 2005). Some of the most advanced readability-based text-retrieval methods stem from the REAP project, which supports learners in searching for texts that are well-suited for providing *vocabulary and reading practice* (Heilman, Zhao, Pino, & Eskenazi, 2008). Indeed, the search for reading materials in support of vocabulary acquisition (see Cobb, 2008, and references therein) is one of the most prominent areas in this domain.

Going beyond readability, based on the insight from SLA research that awareness of language categories and forms is an important ingredient for successful second language acquisition (see Lightbown & Spada, 1999), a wide range of linguistic properties have been identified as relevant for language awareness, including morphological, syntactic, semantic, and pragmatic information (see Schmidt, 1995, p. 30). In response to this need, Ott and Meurers (2010) discuss the design of a *language-aware search engine* which supports access to Web pages based on a variety of language properties.

Complementing the question of how to obtain material for language learners, there are several strands of ATICALL applications which focus on the enhanced presentation of, and learner interaction with, such materials. One group of NLP-based tools such as COMPASS (Breidt & Feldweg, 1997), Glosser (Nerbonne, Dokter, & Smit, 1998) and Grim (Knutsson, Pargman, Eklundh, & Westlund, 2007) provides a *reading environment* in which texts in a foreign language can be read with quick access to dictionaries, morphological information, and concordances. The Alpheios project (<http://alpheios.net>) focuses on literature in Latin and ancient Greek, providing links between words and translations, access to online grammar reference, and a quiz mode asking the learner to identify which word corresponds to which translation.

Another strand of ATICALL research focuses on supporting language awareness by *automating input enhancement* (Sharwood Smith, 1993), i.e., by realizing strategies which highlight the salience of particular language categories and forms. For instance, WERTi (Meurers et al., 2010) visually enhances Web pages and automatically generates activities for language patterns which are known to be difficult for learners of English, such as determiners and prepositions, phrasal verbs, the distinction between gerunds and to-infinitives, and *wh*-question formation. One can view such automatic visual-input enhancement as an enrichment of data-driven learning (DDL). Where DDL has been characterized as an “attempt to cut out the middleman [the teacher] as far as possible and to give the learner direct access to the data” (Boulton 2009, p. 82, citing Tim Johns, 1994), in visual input enhancement the learner stays in control, but the NLP uses “teacher knowledge” about relevant and difficult language properties to make those more prominent and noticeable for the learner.

A final, prominent strand of NLP research in this domain addresses the *generation of exercises and tests*. Most of the work has targeted the automatic generation of multiple-choice cloze tests for language assessment and vocabulary drill (see, e.g., Liu, Wang, Gao, & Huang, 2005; Sumita, Sugaya, & Yamamoto, 2005, and references therein). Issues involving NLP in this domain include the selection of seed sentences, the determination of appropriate blank positions, and the generation of good distractor items. The VISL project (Bick, 2005) also includes a tool supporting the generation of automatic cloze exercises, which is part of an extensive NLP-based environment of games and corpus tools aimed at fostering linguistic awareness for dozens of languages (<http://beta.visl.sdu.dk>). Finally, the Task Generator for ESL (Toole & Heift, 2001) supports the creation of gap-filling and build-a-sentence exercises such as the ones found in an ILTS. The instructor provides a text, chooses from a list of learning objectives (e.g., plural, passive), and selects the exercise type to be generated. The Task Generator supports complex language patterns and provides

formative feedback based on NLP analysis of learner responses, bringing us full circle to the research on ILTS we started with.

Conclusion

In conclusion, the use of NLP in the context of learning language offers rich opportunities, both in terms of developing applications in support of language teaching and learning and in terms of supporting SLA research—even though NLP so far has only had limited impact on real-life language teaching and SLA. More interdisciplinary collaboration between SLA and NLP will be crucial for developing reliable annotation schemes and analysis techniques which identify the properties that are relevant and important for analyzing learner language and analyzing language for learners.

Naturalistic Data

MINNA KIRJAVAINEN AND ANNA THEAKSTON

Introduction

Data collection is an important part of language research. *Naturalistic data* refers to data sampled in as natural as possible situations, in which the interlocutors, topics, or contexts (or any or all of them) are the same or similar to the participants' everyday life. These types of data sets are particularly useful when one wants to diminish potential experimenter effects and study language use in contexts in which participants are less acutely aware that their behavior is being observed. Hence, several sociolinguists have collected speech samples in everyday situations, in which the participants' language closely resembles their language in situations when the researcher is not present (Labov, e.g., 1972a, 1972b; Cheshire, 1982). However, naturalistic data are also valuable in a variety of other (quantitative or qualitative) research contexts. For instance, in monolingual, bilingual, and atypical language acquisition research naturalistic data shed light onto the nature of children's language at different stages of development, as well as forming the basis for hypotheses for experimental investigation. In second language (L2) acquisition research, naturalistic settings can provide a fruitful arena in which to establish a speaker's proficiency under conditions where the anxiety associated with more formal assessments is diminished. For researchers interested in understanding more about how topics, ideas, and views are constructed and elaborated in discourse, naturalistic data provide the raw materials to which discourse or conversational analysis can be applied.

There are two main ways to acquire naturalistic speech data: going out and collecting a new data set or using data that have already been collected. This entry will first give an overview of naturalistic data collection techniques and issues related to that, and then point the reader toward some sources of existing naturalistic corpora.

Naturalistic Data Collection Techniques

If researchers wish to study a language, a target population, or a linguistic phenomenon for which there is no collected corpus available they might want to embark on collecting their own naturalistic data. The most common ways to collect naturalistic data are: (a) to audio or video record interaction onto a tape, disc, or computer hard drive; and (b) to take notes whether in the form of a diary where the participant is observed longitudinally over a period of time or by the investigator taking notes during a single session. Both of these methods have their pros and cons and may be best used by complementing each other. Each will be discussed in turn below.

Recordings

Recordings give a comprehensive account of the participants' language during the recording session(s) because all the interaction is collected. This is essential for some forms of analysis (e.g., discourse analysis). There are also other advantages to having a complete record of an interaction. First, recorded data allow for thorough reliability checks to ensure

2 NATURALISTIC DATA

that the transcription is accurate. Second, provided that the researcher codes the data so that they can be used for a range of analyses (see Coding Recordings/Notes below), recordings allow the researcher to use the same data set to ask a range of different questions by selecting from the data the utterances most relevant to each topic of interest. However, it is useful to bear in mind that the preparation of recorded data for analysis can be time consuming, and consequently rather costly. Thus, recording is best suited for researchers who intend to use the data as the basis for a programme of research.

The transcription and coding of a single hour of recording usually takes around 20 hours, depending on the level of detail included, for example, whether or not the transcript indicates each pause or false start produced, overlap between speakers, and phonetic transcription, and this is in addition to the time needed to collect the data in the first place. A number of factors affect transcription time, including (a) the number of interlocutors in the recording situation, (b) background noise, (c) distance of the microphone from the speakers, (d) the age of the participants (i.e., child vs. adult), and (e) the level of proficiency in the target language. Because getting recorded data ready for analysis is extremely time consuming, it is worth giving serious consideration to how many participants should be included in the study and how frequently recordings should be made. Naturalistic corpus studies, due to the laborious transcription and coding, usually sample only a small number of participants, and there is a trade-off in terms of the amount of data collected from each participant (reliability of the sample) and the number of participants included (generalizability of the results). In the case of children's language development, it is relatively common that one child's speech is collected periodically over several months/years. On the other hand, if the investigator wants to look at a second language speaker's L2 proficiency in terms of native-like pronunciation at a specific point during language learning only one relatively short (e.g., 10 minutes) session might be needed. If the aim is to observe how language develops over time, the researcher must collect samples of speech at appropriate intervals and gather enough data to allow meaningful analysis. But how much data is sufficient? If the aim is to investigate the use of frequent linguistic phenomenon at a fairly general level, then relatively short, infrequent recordings may be adequate. However, if the focus is on low frequency linguistic items, such as passives, which are unlikely to appear in small samples, then short and infrequent recordings (e.g., a 15 minute recording once a month) are unlikely to provide sufficient data. Hence, relatively long recordings collected at regular intervals (e.g., 5–10 hours a week) may be needed (Tomasello & Stahl, 2004).

When recording data, researchers need to decide whether to collect audio or video recordings. The advantages of video recordings are: (a) one can analyze the interaction in terms of gestures and eye-gaze; (b) the speech of non-proficient language users (e.g., children, L2 speakers) can be easier to transcribe when the transcriber can see what the speaker is attending to or doing; and (c) if there are several people interacting during a recording, it is easier to distinguish speakers. However, recruiting participants may be more problematic for video than audio recording, as it may be perceived as less anonymous. Also, the fact that the researcher may need to reposition the video equipment during recordings can increase participant awareness of the process and reduce the naturalness of the interaction in comparison with audio recording. Moreover, video recordings can take longer to transcribe than audio recordings (if coded for non-linguistic interaction).

Note Taking

Note taking can be useful when a specific aspect of language (e.g., passives) is the focus of investigation. A majority of the data collected during a recording is likely to be irrelevant for a focused analysis of this type and the researcher might have to search through

hundreds of hours of data to find a large enough sample of utterances for a meaningful analysis. By taking notes the researcher can selectively write down only relevant utterances making this an efficient data collection method (it is virtually impossible, however, to take notes of an entire interaction accurately due to the speed and volume of speech data).

A potential advantage of note taking is that it can generate data that are more immediately available for analysis. First, it might not be imperative to type handwritten notes into electronic form because the utterances of interest have been preselected and the problem of finding the relevant utterances in the data is removed, although many studies will benefit from having handwritten data coded in electronic form. Second, transcription time is reduced because the data are transcribed during data gathering so no time is spent on listening to/watching the recordings. However, a disadvantage of note-taking methods is that they do not allow for reliability checks to be conducted on the transcription of utterances and thus allow for a greater margin of error. For this reason, a systematic note taking protocol needs to be constructed to define the kinds of utterances that are relevant to the investigation and to address how to record any potential ambiguities in the speech of an informant (e.g., see Naigles, Hoff, & Vear, 2009, for detailed information regarding the training of note-takers in a longitudinal diary study of children's early verb use).

When it comes to the sampling, as with recordings, both longitudinal and cross-sectional note-taking studies are possible. Because all of the data collected by note taking can be directly relevant to the research question (e.g., data can focus on a specific linguistic feature) and because transferring the notes into an electronic form is relatively quick, note taking gives more scope for frequent and long data-collection sessions than recordings (e.g., 3 hours of observation a day), and the inclusion of several participants.

Coding Recordings/Notes

When transcribing data into electronic form one can use existing transcription systems such as CHAT (Codes for Human Analysis of Transcripts) (<http://childes.psy.cmu.edu/>), ELAN (<http://www.lat-mpi.eu/tools/elan/>), or PRAAT (doing phonetics by computer) (<http://www.fon.hum.uva.nl/praat/>) that allow the use of computerized coding systems to prepare the data for analysis (see <http://talkbank.org/software/> for descriptions of other operating systems suitable for quantitative and qualitative data analysis and for links to further information). Researchers will need to consider whether an existing transcription system meets their requirements. For example, CHAT is excellent for the transcription of spoken language, whereas ELAN is more useful when transcribing audio and video data if the researcher wishes to code a range of complex phenomena such as gesture/speech overlap, or inputs from multiple video recordings of the same scene. A key benefit of using an established transcription system is that the data are more readily utilized by other researchers, promoting data sharing.

Once the data have been transcribed, or during transcription, researchers typically want to code it for specific linguistic features. The detail one needs to include in the coding depends on the intended level of analysis and the particular focus of the study. The coding for an analysis of pragmatic aspects of the interaction would be very different from those required for a phonetic analysis or an analysis of grammatical structure. General information about the recording, such as age of participant(s), language(s) spoken, and a way of identifying the informants (e.g., Child, Mother, or possibly a first name) can be easily coded in the beginning of each file, allowing researchers at a later date to select which transcriptions are relevant for a given analysis. Example 1 gives a slightly truncated illustration of what general detail might be included in transcripts. For more information about coding for specific details in CHAT see MacWhinney (2011).

Existing Databases

If a researcher wants to study naturalistic corpora but does not have the time/resources to collect their own data, several databases already exist which can be purchased online, for example, British National Corpus (BNC) (www.natcorp.ox.ac.uk/) and SWITCHBOARD (<http://www ldc.upenn.edu/Catalog/>), or are available to download free of charge, for example, CHILDES (Child Language Data Exchange System) (<http://childes.psy.cmu.edu/>). This means that anyone can access large datasets without having to collect their own data. However, it is imperative that researchers fully familiarize themselves with any given corpus before embarking on data analysis as certain aspects of spelling and coding may differ between corpora and ongoing developments including automated coding practices may mean that search commands need revising in accordance with global changes to any database. When it comes to ethical issues, the use of existing naturalistic corpora is convenient as the relevant consents were obtained by the original researchers.

CHILDES (MacWhinney, 2000) is a database set up by Catherine Snow and Brian MacWhinney in the 1980s. The aim was to unify the different transcription and coding procedures used in child language research and bring together a range of datasets donated by different researchers, making them available for use by researchers worldwide. CHILDES has naturalistic corpora on a number of different languages, on both mono- and bilingual children. It also has clinical data, for instance, from autistic children and children with specific language impairment.

The BNC contains naturalistic data (in addition to written language) in the form of informal conversations, as well as more formal language samples. The informal conversations predominantly include British-English speakers using a number of geographical and socioeconomic language varieties. Both adult and child data are available.

SWITCHBOARD consists of over 2,400 spontaneous telephone conversations of on average six minutes duration between unacquainted American-English speakers ranging largely between the ages of 20 and 60 years. The conversations cover a range of topics (e.g., football, public education) and represent all major dialects of American-English.

Analysis of Data

Programming languages such as CLAN (Computerized Language Analysis) (<http://childes.psy.cmu.edu/>) and PERL (www.perl.org/) can be used for data analyses. CLAN is compatible with CHAT (see above) and extracts, for instance, frequencies of words and structures, co-occurrence of particular words, mean length of utterances, and interactional and morphosyntactic analyses. Its use is relatively straightforward and one does not need to be a computer scientist to be able to write the search commands. Example 2 shows a basic command which extracts the frequency (freq) of all word-types in the child's speech (+*chi) from selected transcription(s) (@ represents selected input file[s]). One could modify this

command in various ways, for example to limit the search to a particular word(s) or grammatical class, to sum frequencies across a range of files, or to include additional speakers. One can also modify the output of the command, for example, to order the output either alphabetically or by frequency, or to sum frequencies across a range of input files. PERL is somewhat more versatile but requires slightly more advanced programming skills. The BNC has its own search tool.

(2) freq +t*chi @

Programming languages allow one to search for instances of particular linguistic features in large (or small) data sets with relatively little effort. Although the researcher will need to check their search commands carefully to ensure that they operate as expected, and might subsequently manually search the output (i.e., the utterances matching the search criteria) to eliminate nontarget structures, nevertheless, this is still considerably more efficient than a manual search.

Conclusion

When embarking on a naturalistic data analysis, especially if large datasets are needed or infrequent linguistic phenomena are to be investigated, the best place to start is to search online to establish whether relevant naturalistic corpora already exist (e.g., check the Web sources provided above). In the case of collecting one's own naturalistic data, the specific research question(s) and focus of the analysis will need to determine the method and frequency of data collection and coding, and the number of participants included in the study.

Needs Analysis

MICHAEL H. LONG

A Rationale for Needs Analysis

Learner goals and needs can differ widely, both within and across groups. Some students may require advanced proficiency in the language spoken in a country to which they have immigrated, or to which they plan to emigrate. Another group may only need to be able to read the professional or scientific literature in their field. Other learners may require proficiency in three or all four skills to gain access to higher education programs overseas, for occupational purposes, or for vocational training. These and many other language-learning goals will require different levels of proficiency, different strengths in receptive and productive skills, knowledge of different genres, registers, vocabulary, and collocations, and different pragmatic abilities. A needs analysis (NA) will identify learner goals and communicative language needs, and thereby make appropriate program design and delivery possible.

Units of Analysis in NA

The first decision to be made concerns the optimal unit of analysis. Reflecting the traditional synthetic approach to language teaching, one approach is to examine sample spoken or written texts students have to negotiate, to identify the frequencies of linguistic features and structures. This process can provide useful information, but tends to result in checklists similar to the table of contents of pedagogic grammars, and, crucially, with the connections between form, function, and task lost. It is little use knowing that a particular group of learners needs to master certain forms because they occur frequently in a given domain without knowing how they are used there, especially since domain-specific uses often differ from those modeled in generic (no purpose) language teaching materials. Cathcart (1989), for example, found that present simple verb forms in doctor–patient encounters tended to occur not in describing habitual action sequences, but in conditionals and other complex structures (“If she gets another one, we’ll put her on . . .”). Modals occurred mostly as hedges (“It should fade away,” “She may not be able to eat”) and to express possibility (“We may not need to . . .”), not, for example, for giving advice (“You should drink a lot of water”), as modeled in some ESL materials.

In an attempt to deal with the form–function issue, as part of the work of the Council of Europe applied linguistics team for the unit credit system project, Richterich (e.g., Richterich & Chancerel, 1977/1980) took as his starting point the target situations in which a particular type of worker would be involved, subsequently broken down by the participants, or agents, communicative functions, objects and means, as well as many subcategories of each. The work was mostly based on intuition, as was a more formal version of target situation analysis, Munby’s Communication Needs Processor (CNP) (Munby, 1978), a model influenced by Halliday’s writings on language and meaning potential and Hymes’s work on communicative competence.

While an improvement over purely linguistic analyses, there were problems with this approach. First, it is not clear that language use can be predicted from situation or communicative event, or that it needs to be. Second, even if target linguistic forms could be specified reliably and validly using the CNP, their use as syllabus content is of doubtful validity from an acquisition standpoint, since the result is a *synthetic* linguistic syllabus. Forty years of SLA (second language acquisition) research findings show that learners cannot learn a language one structural or functional linguistic unit at a time, on demand, in an externally dictated sequence. Third, textbook writers' intuitions about language use have routinely been found to be inaccurate (see, e.g., Williams, 1988; Cathcart, 1989; Bartlett, 2005). To be useful, an NA must be based on empirical observation of one or more kinds.

The obvious solution is to adopt *task* as the unit of analysis (Long & Crookes, 1993). Reliable information about tasks is available from task-based occupation analyses and other ready-made sources, and from domain experts, who are usually very knowledgeable about the frequency and criticality of tasks performed in their work. Second, tasks constitute natural units around which to organize communicative classroom lessons, with transfer of task-related "scripts" to target situations outside the classroom more likely than transfer of decontextualized linguistic forms. Third, the target tasks identified as frequent, critical, or both, will provide input to a task-based syllabus, as part of an *analytic* approach to language teaching, with a *focus on form*, which, unlike use of synthetic syllabuses and methodology, is broadly consistent with SLA research findings on how adults learn languages (Long & Robinson, 1998; Long, 2009).

Stage 1 of a Task-Based NA: Identifying Target Tasks

Task-based needs analyses are becoming more common (see, e.g., Chaudron et al., 2005; Gilabert, 2005; Jasso-Aguilar, 2005). The first step is to identify the *target tasks* for a learner or group of learners. As in virtually any area of scientific inquiry, the reliability and validity of an NA are likely to be improved if the analyst utilizes multiple sources of information and multiple methods of obtaining it, preferably triangulating among methods and sources.

Sources include published and unpublished literature—everything from journal articles reporting findings of previous NAs in the same or similar domains to the one currently of interest, to primary sources, such as course syllabuses and reading lists, government publications describing the work performed in numerous occupations (e.g., the US *Dictionary of Occupational Titles*), job descriptions, training manuals, trade certification tests, professional examinations, and union contracts. Especially crucial sources are domain experts, who are insiders. In an NA for airline flight attendants (FAs), for example, they would include experienced FAs, and trainers and evaluators of FAs. In an NA for engineering students preparing for a graduate program overseas, they would include engineering faculty members, lab technicians, and academic advisors in the program concerned.

Methods range from unobtrusive, open-ended procedures, such as logs and participant and nonparticipant observation, through unstructured, semi-structured, and structured interviews, to surveys and questionnaires. It is important that methods be sequenced appropriately, with open-ended methods used first. They provide depth to a study and will not preclude analysts discovering things they are unaware they do not know. Such procedures tend to be more labor-intensive, so they can typically be used only with representative (ideally, stratified random) samples of the target population. More closed procedures, such as questionnaires, provide an analysis with breadth, or coverage, and serve to ascertain the extent to which needs tentatively identified hold across larger samples, or, in some cases, an entire target population. For detailed descriptions of these and many other sources and methods available, sample studies utilizing them, and discussion of their relative strengths and weaknesses, see Brown (2009) and Long (2005).

Stage 2 of a Task-Based NA: Target Discourse Analysis

Having identified the target tasks for a learner or group of learners, the second step is to secure representative samples of *target discourse*, or language use, surrounding accomplishment of those tasks (see Chaudron et al., 2005). Recordings may be made of spoken texts, such as talk between doctors and patients, doctors and family members, doctors and nurses, nurses and patients, and among doctors. Even when concerning the same tasks, such as a medical diagnosis or prognosis, the texts will vary in register, discourse structure, form–function mappings, lexical frequency, density and range, and collocations. Task-related discourse can also vary cross-culturally, and in the degree of presupposed knowledge, information density, ellipsis, and intertextuality (Ventola, 1983; Medway & Andrews, 1992). Analyses may also need to be conducted of written texts—perhaps the forms to be filled out to open a bank account, obtain a library card, or apply for a job vacancy; e-mail messages and faxes in the workplace; the readings and term papers required to complete a school or university course; or the written professional examinations required for certification of competence in many occupations and for entry into most professions.

From NA to Syllabus

Both the target tasks and target discourse samples will usually have to be modified for pedagogic purposes. Less complex versions of target tasks, that is, *pedagogic tasks*, will be required in the early stages of most courses where students are pre-experience, or at elementary levels of language proficiency. Sequences of pedagogic tasks, gradually increasing in (task) complexity, will constitute the core of a task syllabus (Robinson, 2001). *Elaborated (not simplified) versions of target discourse* will be the other major component (see, e.g., Bartlett, 2005; Chaudron et al., 2005). Unlike linguistic simplification, elaboration can increase comprehensibility without bleeding input of the new target language forms learners need to acquire, and provide them with more psycholinguistically defensible target language exposure than genuine, so-called “authentic,” texts (Long & Ross, 1993; Long, 2007).

Needs Analysis and Syllabus Design for Language for Specific Purposes

HELEN BASTURKMEN

Introduction

Language for specific purposes (LSP) courses are designed to meet the specific needs of learners (Dudley-Evans & St John, 1998, p. 4). The courses are designed to help learners function linguistically within a particular academic, professional, or workplace environment, and generally the syllabus is derived from an analysis of the needs of the learners in relation to their target environment. The analysis of learners' needs is thus a key process in the design and ongoing revision of the LSP syllabus. This entry discusses the importance of needs analysis in LSP, identifies trends in the practices and methodologies used, and examines how the results of needs analysis can be used to inform the design of the LSP syllabus. Although needs analysis is often viewed as essentially procedural, it is not without theory, nor is it devoid of controversy and debate. The final section discusses the role of theory in needs analysis and examines social-political, educational, and methodological concerns.

The Role and Importance of Needs Analysis

Needs analysis is widely seen as a defining characteristic of LSP and as a key process in the development and revision of LSP courses (Dudley-Evans & St John, 1998; Basturkmen & Elder, 2004; Kim, 2008). In this process, course developers investigate what learners need to know or be able to do in the target language in order for them to function effectively in their chosen profession, work, or study area. This is referred to as *target situation analysis*. In devising an LSP course for a group of students of accounting, for example, the teacher or course developer will typically carry out a target situation analysis to identify the tasks and functions the learners will need to perform and, in relation to these, the language competencies they will require, such as areas of language knowledge (for example, particular semantic fields and genres) and linguistic skills. A needs analysis for students of accounting may indicate that the learners need to be familiar with vocabulary on topical areas (such as *loans* and *asset management*) and written genres (such as *financial statements* and *market reports*), and will need to draw on linguistic skills (such as *making notes while listening to lectures*) in order to make the most of their accountancy studies. In addition to target situation analysis, the teacher or course developer may conduct a *present situation analysis* to identify the learners' current ability to perform functions and tasks in the target situation. This involves assessing the learners' current level of competence with the level required for successful participation in their profession, work or study area. The information obtained from the analyses is used in designing the course, for example, by organizing the syllabus wholly or partly around the areas of need identified.

Although needs may be analyzed in the design of syllabuses in general language teaching (Feez, 1998; Graves, 2001), needs analysis is considered critical in the design of LSP

2 NEEDS ANALYSIS AND SYLLABUS DESIGN FOR LSP

syllabuses (Nunan, 2001, p. 57). There are a number of reasons for this. One reason relates to the purposes of LSP. LSP courses are established not so much for the general value that knowing the target language may have for the learners as for the specific value that knowledge of the language will have in helping learners gain entry to, or advance in, their chosen area (discipline, profession, or workplace). Thus, teaching in LSP is focused on needs related to that area. Another reason needs analysis is critical is related to the duration of LSP courses. Unlike general language teaching courses, which may be long-term, LSP courses are often relatively short-term. Given the usual time constraints, it is essential that time is used effectively in teaching LSP and thus instruction is focused only on the areas of language and skills of direct relevance. A further reason is the nature of learners' needs in LSP. It is feasible to organize LSP instruction around needs because the learners have shared needs, since they are all currently studying or working in, or hoping to gain entry to, a particular field or discipline. It is thus possible to identify a set of common needs to a greater extent in an LSP situation than it would be in a general language teaching situation.

Some writers see needs analysis as the defining characteristic of LSP, the characteristic that sets LSP apart from general language teaching. Dudley-Evans and St John (1998, p. 1) argue that a theory of ESP "could be outlined based on either the specific nature of the texts that learners require knowledge of, or on the basis of the needs-related nature of teaching." The key role of needs analysis (in English for specific purposes, ESP) is described by Belcher (2006) as follows:

Like other educational endeavours, ESP assumes there are problems, or lacks, that education can ameliorate, but unlike many other educational practices, ESP assumes that the problems are unique to specific learners in specific contexts and thus must be carefully delineated and addressed with tailored-to-fit instruction. ESP specialists are often needs assessors first and foremost, then designers and implementers of specialised curricula in response to identified needs. (p. 135)

Conducting needs analyses and designing the kinds of "carefully delineated" and "tailored-to-fit instruction" described by Belcher place considerable demands on the skills and time of the teacher or course designer.

Trends in Practices and Methods

Over the years, the practice of needs analysis in LSP has been subject to change and development. The scope has become broader and what was once seen as a relatively simple pre-course procedure to analyze language and communication in the target situation (target situation analysis), has become increasingly sophisticated over time (Tajino, James, & Kijima, 2005).

Early needs analyses tended to focus on the language requirements of the target situation to establish priorities in terms of the situations, functions, tasks, or skills needed (West, 1997, p. 71). Over time, the scope has widened to include present situation analysis (assessment of the learners' current ability to perform the skills, tasks, or functions) and investigation of learners' *subjective needs* (what learners would like to learn), in addition to investigation of *objective needs* (needs identified through target situation analysis), investigation of *learning needs* (learners' preferred learning styles and strategies, and preferred instructional methods), and *means analysis* (assessment of the teaching context, including how the course will be run and the LSP background of the teachers). At present, needs analyses in LSP generally include target situation analysis and some or all of the other types of analysis shown in Table 1.

Table 1 Types of analysis

<i>Type of analysis</i>	<i>Aims to identify</i>
1 Target situation analysis	Language-related tasks, activities, and skills that the learners should ideally be able to perform in the profession, work, or study situation they wish to enter or advance in
2 Present situation analysis	The level of the learners' ability to perform the language-related tasks, activities, and skills activities in relation to the demands of the target situation
3 Learner factor analysis	Learner factors, such as their motivation, how they learn, and their perceptions of needs and wants in relation to the LSP course
4 Teaching context analysis	Factors related to the environment in which the LSP course will run and what the course and teacher can realistically offer

Conventional methods of inquiry include the use of questionnaires and interviews to elicit the perceptions of learner needs as seen by the various stakeholders (learners, teachers, institutional representatives, and employers) and concomitant use of linguistic analysis of communication in the target discipline, profession, or workplace. The latter may take the form of a functional or speech-act analysis in the case of spoken communication and text-based analysis in the case of written communication. Although these methods remain popular, others have also emerged. One trend is the investigation of real-world tasks in the target situation. Tasks, units not defined by linguistic criteria, have been the unit of analysis in a number of studies (Long, 2005; Cowling, 2007; Thomas, 2009). A second trend is the use of multiple sources and methods in the collection and triangulation in the analysis of data (Jasso-Aguilar, 1999; Gilabert, 2005; Long, 2005). Increasingly, learner perspectives are the focus of investigation in addition to the perspectives of institutional representatives or employers. The needs analyst may, for example, seek current LSP course members' views of their needs or difficulties, or contact former LSP course members now working or studying in the target environment.

Recent years have seen the emergence of ethnographic approaches (see, for example, Giminez, 2001; Northcott, 2001; Molle & Prior, 2008). Ethnographic needs analyses aim to reach an in-depth understanding of communication in the target community, in order to gauge insider perspectives on the role of communicative practices, and community expectations and values for these practices. In line with ethnographic inquiry generally, analysts using this approach draw on methods such as observations of communicative events in the target environment and in-depth interviewing in their investigations. Inquiry into such values and expectations is often pursued alongside linguistic analyses of texts, including genre analysis and corpus linguistics. For example, Ding (2007) investigated the personal statement and the letter accompanying applications for graduate study to medical and dental schools. Ding had found that applicants usually had little knowledge and understanding of the forms and functions of this genre and expectations held for it by selection committees at the graduate dental and medical schools. To investigate these values and expectations, Ding interviewed professors in charge of admissions at medical schools and found *inter alia* that the professors expected the letters to include evidence of commitment to medicine or dentistry and to discuss the applicants' specific, first-hand experiences of helping people. In conjunction with this thrust of the inquiry, Ding conducted a genre- and corpus-based analysis of samples of personal statements.

Although a number of recent needs analyses can be characterized as having a narrow focus on needs in particular discourse communities, a needs analysis may also have a broad focus on the requirements of learners across contexts (Taillefer, 2007) or across disciplines (Kim, 2006). In such cases, surveys are often used. For example, in a study investigating the listening and speaking needs of East Asian graduate students in the USA, Kim (2006) used a Web-based questionnaire to survey 280 students in a US university context. The questionnaire included items asking the students for their perceptions of their listening and speaking needs for university study, their difficulties in meeting these needs, and the specific listening and speaking skills they considered important for academic success.

From Needs Analysis to Specification of Syllabus Content

An important consideration in the design of syllabuses in general concerns the issue of what content is to be covered in the course and the sequence in which it is to be covered. In general language teaching, determining content may be related to a number of considerations, one possible consideration being disciplinary, professional, or workplace needs. In LSP, however, such needs are generally of primary importance in determining course content.

The results of needs analysis are generally used to determine the objectives for the LSP course and to specify the sequence of instruction or content (language, tasks, activities, and skills) to be covered in the course. In LSP, writers distinguish between two types of content: *real content* and *carrier content* (Dudley-Evans & St John, 1998; Belcher, 2006). Real content refers to the aim of instruction, what we want our students to learn, and carrier content refers to the means of delivering the real content. Returning to the example of the students of accounting introduced earlier, our aim might be to familiarize our learners with vocabulary related to market reporting, and we could select a market report-type text from a newspaper to “carry” the content. In the remainder of this discussion, the word “content” is used to refer to “real content.” The course developer might opt for a multi-strand syllabus combining different elements including grammar, lexis, functions, and tasks related to the needs identified in the needs analysis. For example, the vocabulary strand in the first module of the course might focus on *assets* and in the second on *loan management*.

How the course developer determines course content often depends not just on areas of need identified in the needs analysis but also on views about language and language learning. The course developer may structure the syllabus around one particular feature of language that is seen as primary. For example, Feez (1998) describes the development of a text-based syllabus reflecting the view that “language occurs as whole texts which are embedded in the social contexts in which they occur and people learn language through working with whole texts” (p. 3). In this view, texts are the units by which the syllabus is organized. The content of the syllabus is based on texts selected in relation to learner needs and the social contexts the learners aim to access. Taking this view, the developer of the course for students of accountancy could devise a syllabus around text types with module one as *financial statements* and module two as *market reports*, with language and skills content related to the texts at hand and to vocabulary and skills involved in reading financial statements.

Views of learning may influence not only how the results of needs analysis are translated into content but also the teaching approach delineated in the syllabus. Parkinson, Jackson, Kirkwood, and Padayachee (2007) report the development of a reading and writing course for foundation year (that is, preparation for first year) university students. This course was organized around four genres (text types) including the laboratory report. In developing

the course, the writers report being guided partly by findings from a needs analysis but also by perspectives on learning. Specifically, they were guided by the view that it is only when students read with comprehension that they can write effectively, and by the notion of scaffolding learning from sociocultural theory (p. 446). This view led the writers to partially rewrite some texts for use in instruction, such as research articles, so that the texts were not too difficult for their students in terms of vocabulary and concepts (p. 447).

The Role of Theory

Often it is the procedural aspects or results of a needs analysis that are highlighted in the literature, and this may give the impression that needs analysis is not a theoretical topic. However, this is not the case (Robinson, 1991; West 1994; Hyland, 2008). Hyland (2008) argues that needs analysis is “like any other classroom practice in that it involves decisions based on teachers’ interest, values, and beliefs about teaching, learning and language” (p. 113). As seen above, teachers’ or course developers’ views of learning may be used alongside results of needs analysis in determining the syllabus. Their views may be used in the selection of units for the organization of the syllabus, determining the way content is combined and the choice of approach. Such views also play a role in determining what is investigated in a needs analysis. It has been argued that “any system of needs analysis is related to the theory of the nature of language” (West, 1994, p. 2). One needs analyst may view language as primarily a set of speech acts (functions) and will seek to identify the language functions used in a particular environment. Another analyst may view language primarily in terms of a set of semantic resources and aim to identify high-frequency lexical items in the same environment.

Not only can language theories inform needs analysis (for example, by influencing the selection of the unit) the analyst chooses to investigate) but it is possible that needs analysis may be able to contribute to theory. Molle and Prior (2008), conducting a genre-based needs analysis of student writing in university settings, found a number of complexities in the written texts in their setting that challenged the notion of genre on which the study had been based. This finding led the researchers to reconceptualize their understanding of genre and offer a perspective of genre in university settings as a multimodal set of systems merged within academic activities (p. 563).

Views of language learning may also influence the analyst in decisions about what to investigate. Räsänen (2008) describes a transition in her teaching context from a view of learning as acquiring knowledge of language systems to a view of learning as the development of competencies in language-related skills, and in line with this reorientation, a subsequent investigation of core language-related skills as part of the process of LSP course development. As argued by Robinson (1991),

The needs that are established for a particular group of students will be an outcome of a needs analysis project and will be influenced by ideological preconceptions of the analysts. A different group of analysts working with the same group of students, but with different views on teaching and learning, would be highly likely to produce a different set of needs. (p. 7)

Issues in Needs Analysis

Most needs analysts limit themselves to reporting findings and few discuss issues in needs analysis (Gilabert, 2005). Although limited, there has been some discussion of issues associated with needs analysis in the literature, however. This section examines some of the

sociopolitical, educational, and methodological concerns that have been raised in relation to needs analysis and needs-based course design.

A number of sociopolitical concerns have been raised. One argument is that needs analysis may serve institutional rather than learner interests, and in effect marginalize learners. Needs analysts might over-rely on information from institutional representatives who have definite expectations about what the learners should be able to do (Auerbach, 1995). By developing courses around needs, designers are in effect training learners to fit into the communicative practices of linguistically privileged in-groups. Needs analysis may at first sight seem to be a neutral endeavor, but in fact, it is a means by which institutions can try to get others to conform to their own established communicative practices (Benesch, 2001). Workplace needs-based LSP courses may serve as a covert means of channeling immigrants into marginal occupations. By ensuring the learners only have sufficient English to perform specific low-wage jobs, such courses in effect deprive learners of the opportunity to develop the general language competence that might enable them to move beyond these jobs (Tollefson, 1991).

To avoid an overemphasis on institutional interests, many needs analysts do not limit their investigation to the perspectives of the institutions, but investigate the views of various stakeholders. See, for example, studies by Jasso-Aguilar (1999) and Bacha and Bahous (2008). Analysts may find, however, that perceptions of needs vary, and in these cases the course developer has to decide whose perceptions to take into account in designing LSP instruction or otherwise try to synthesize divergent perspectives (Jasso-Aguilar, 1999). In such circumstances, institutional expectations might exert more pressure on the course designer than those of the learners or workers.

Basing courses on the language requirements of the target environment raises educational concerns. Language needs are not learning needs, and although learners may need to use certain language structures or features in their target environments, this does not mean that they are ready to acquire these structures or features (Hutchinson & Waters, 1987). By developing needs-based instruction, it is generally assumed that the learners will find the course content relevant and thus motivating. But this may not be the case. For example, engineering students may need to work with texts concerned with technical matter. The texts LSP teachers (other than those who have an engineering background or understanding of engineering beyond that of the layperson) might select to use in the classroom may be technically low-level and not prove interesting to the learners. It is difficult to justify needs-based courses except with reference to relevance and motivation. A further argument is that needs-based LSP courses can lead to language training rather than language education. Learners are trained to perform a restricted repertoire of the language rather than develop underlying linguistic competence of the language because they are deprived of its generative basis (Widdowson, 1983).

The methods used in needs analysis have been subjected to scrutiny. Although needs analysts often seek to gauge the learners' perceptions of their needs, the learners may not be reliable sources of information about their needs, particularly if they are relatively unfamiliar with the job they are to perform or subject they are to study (Long, 2005). Analysts also try to gauge the perceptions of other stakeholders such as employers and institutional representatives, but they, like learners, may not have a sophisticated knowledge about the language and metalanguage needed to describe target situation language use and the nature of linguistic difficulties in a meaningful way.

The methods used in a needs analysis may affect the results. Long (2005), in a study to identify the needs of airline cabin crews, compared different methods of data elicitation in an attempt to see how the choice of method impacted on the data obtained and ultimately on the results of the needs analysis. Following Long (2005), Thomas (2009), in a study to

identify language-based tasks of engineers within a particular civil engineering company, compared two methods of data elicitation: oral interviews and written introspection. Thomas found that the written introspections elicited a greater range of tasks than the interviews but the interviews elicited more detail and complexity of task descriptions than the introspections. Such results support calls for the use of multiple methods and triangulation in needs analysis (Jasso-Aguilar, 1999; Gilabert, 2005; Long, 2005).

Conclusion

To conclude, needs analysis is seen as a defining, if not the defining, characteristic of LSP. Although long recognized as a fundamental characteristic, the practice of needs analysis in this field has changed over time: the scope of investigation has widened and the methods used have become ever more varied. The focus of needs analysis has been expanded from a relatively narrow investigation of the linguistic requirements of the target situation to a wider investigation that also includes investigation of needs related to learner factors and teaching context.

The importance of needs analysis lies in the potential of its findings to inform the development of the syllabus of the LSP course in question. As Long (2005) argues, findings from any particular needs analysis are restricted to the setting of the study and cannot be generalized to a wider audience. What may, however, be of interest to the wider audience is the choice of methods, and as we have seen, methods in this area have become increasingly sophisticated over time.

Neurobiological Foundations for Second Language Acquisition

NAMHEE LEE

Introduction

The distinction between declarative knowledge and procedural knowledge has played an important role in second language acquisition (SLA) theory and research. The former is memory for facts about the second language (L2) (formal rules, lexical items, and formulaic speech). The latter involves memory for skills and automatized cognitive and motor programs. Both forms of knowledge are important in natural and instructed SLA. At the very least, declarative knowledge is necessary for the acquisition of vocabulary, and procedural knowledge is necessary for learning grammatical sequences and discourse processes. Most of the discussion of these two types of memory in the SLA literature has been at the linguistic and psychological levels (O'Malley & Chamot, 1990; Schumann, 1990; de Bot, 1992; Ellis, 1994; Towell & Hawkins, 1994; Dekeyser, 1997, 2001).

Paradis (1994) presents an excellent neuropsychological account of declarative and procedural learning, indicating that the hippocampus subserves the former, and the basal ganglia underlies the latter. Ullman et al. (1997; Ullman, 2001) have proposed the declarative/procedural model, which supports the roles of the hippocampus and the basal ganglia in language processing. Ellis (2001) provides a detailed account of working memory and chunking for language acquisition and use. The purpose of this entry is to examine the neurobiological foundation of these memories and their implications for SLA.

Semantic Memory and Its Neural Structure

Declarative memory (DM) is divided into semantic memory and episodic memory. Episodic memory concerns autobiographical events that have taken place during an individual's lifetime, and semantic memory encompasses factual knowledge about things, places, time, concepts, odors, and so forth. The neural mechanism of semantic memory is well known (Parent, 1996; Squire and Kandel, 1999) and is illustrated schematically in Figure 1. When human beings perceive the outer world, sensory input is relayed to the primary sensory areas in the neocortex. Since multiple sensory modes are employed in perceiving the world, the perception is likely to be related to multiple sensory areas. For example, when we see a dog, we process visual, auditory, olfactory, and tactile information regarding the dog, and this information is in turn passed on to the association areas in the neocortex. From the association areas, the information then travels through diverse structures of the medial temporal lobe. First, it passes through either the parahippocampal cortex or the perirhinal cortex and arrives at the entorhinal cortex. The entorhinal cortex relays the information to the hippocampus. After the information arrives at the hippocampus, it makes a return trip back to the neocortex through all the structures of the medial temporal lobe it passed through on the incoming trip. While information travels through this loop, the synapses between participating neurons are strengthened by the mechanism called long-term potentiation and protein synthesis (Schumann et al., 2004).

2 NEUROBIOLOGICAL FOUNDATIONS FOR SLA

Figure 1 The neural mechanism of semantic memory

Evidence of the Hippocampus's Involvement in Semantic Memory

The first study that demonstrated the hippocampus' involvement in all DM, including semantic memory, was performed by Brenda Milner and William Scoville in 1957. In an attempt to cure a patient, H.M., who suffered from a severe case of epilepsy, Scoville removed a part of the medial temporal region of both hemispheres, which included the hippocampus and surrounding structures. After the surgery, H.M.'s epilepsy was cured, but he could not form new DMs. He forgot everything associated with the event just several seconds after its occurrence. For example, he could not remember his doctor even though they met every day, and the doctor had to introduce himself anew every time. H.M. was living with just a several-second time span in terms of his memory. Strangely enough, however, Milner and Scoville discovered that H.M.'s memories for events that had happened in the distant past remained intact. H.M. was also able to learn how to play a new tune on the piano even though he couldn't remember learning it. When he was asked how he knew the tune, he answered that he didn't remember but that he just did. In summary, H.M. lost his ability to form new DMs, but retained both the ability to form procedural memory (PM) and DMs established before the surgery. Since H.M.'s case was reported, numerous cases of patients with lesions in the hippocampus who show similar symptoms have appeared in the literature (e.g., Squire & Alvarez, 1995). All these studies confirm that the hippocampus is involved in forming new DMs (Milner, 1999).

Consolidation of Semantic Memory and Its Implications for SLA

No clear agreement exists among researchers on the issue of how an item of semantic memory is consolidated and finally stabilized. The most prominent theory, however, is multiple trace theory. Nadel and Moscovich (1997) suggest that when a sensory input is relayed from the cortex to the hippocampus, a trace is established between a group of neurons of the hippocampus and those of multiple cortical areas that together store a representation of the item. The group of neurons in the hippocampus functions as a pointer that indexes the cortical neurons. This pointer also works to connect the cortical neurons together gradually. The establishment of the trace is actualized through molecular changes such as long-term potentiation and protein synthesis in the participating neurons and their synapses.

This initial memory can be strengthened over time when it is rehearsed and retrieved. Each time the memory is reactivated, a new trace is formed between new cortical areas and the original hippocampal area, since the content of the memory can be slightly different each time it is activated. When a memory is retrieved a number of times, the memory can be stabilized, and be available to the individual throughout his or her life. When a memory is stabilized to this extent, the connection between the cortex and the hippocampus may be lost, but the transcortical connections between participating cortical neurons remain strong enough to support storage and retrieval of the memory without the help of the hippocampus. In short, a memory is formed initially through the cortico-hippocampal connections, then consolidated through multiple traces within the cortex.

Semantic memory applies to our learning of vocabulary and explicitly learning grammar and phonological rules. Explicitly learning a grammar rule and being able to use it correctly and automatically do not necessarily mean the same thing. Some non-native English speakers correctly execute a grammar rule without consciously knowing it. Others may have learned the grammar rule in an English as a second language (ESL) class and know that such a rule exists but still make errors implementing it when they speak. The former group has no semantic memory of the particular grammar rule, but has PM. The latter, on the other hand, has semantic memory but no PM for the rule that has been taught to them.

Knowledge of the neurobiological system underlying DM is helpful in explaining a number of aspects of individual differences in L2 learning. The bilingual lexicon has been shown to be distributed throughout the cortex (Ojemann & Whitaker, 1978). Since the features of the lexicons are different and learners use different strategies, the indexing of information would be distributed differently for the two languages and across subjects. Such differences could be contributed to by differences in the semantic features associated with the lexical items in the two languages. The differences could also result from different learner strategies. Finally, the differential experience of language learners may also lead to the dispersed distribution of the bilingual lexicon. Classroom teaching strategies may promote a dependency on contextual, visual, or movement cues to help with learning (Littlewood, 1994; Krashen, 1995). This would result in a neurobiological representation in which the visual, spatial, or contextual traces are strongly associated with the cortical regions.

Understanding the neuroanatomical system underlying DM can also help explain the individual differences in levels of proficiency among adult language learners. Here, spatial, visual, auditory, and contextual cues play a key role, as does rehearsal. For example, the contextual cues mentioned above are not only significant in the extent of the neurobiological representation. If the contextual cues are activated each time the word is activated, new traces for the contextual cues will be made each time, thus building not only an extensive network, but a strongly activated representation. So these cues, which augment the meaning of the word, will be activated each time, perhaps helping the learner use the word. This could contribute to an ability to learn the word more easily or to remember the word better.

These principles can affect proficiency beyond lexical learning. Fossilization, a lack of complete proficiency, and the role of anxiety in adult language learning are well-studied phenomena (e.g., Ellis, 1994). How fear and anxiety can affect learning could be explained in the context of the neural system for DM. The strength of a memory can be affected by state of a memory; that is, by whether it is activated or not (e.g., Miller & Matzel, 2000; Millin, Moody, & Riccio, 2001). It is possible that disruptions that exist in the learning situation, such as anxiety or stress or even competing information, could also disrupt the consolidation of lexical items or grammatical rules.

Procedural Memory

PM is concerned with learning motor and cognitive procedures. We acquire this type of memory through the repeated execution of a task. This memory is what we use, for example, when we learn how to play a musical instrument, how to dance, how to play a sport, how to speak our language, and so forth (Fabbro, 1999). Numerous activities in our daily lives are learned and performed procedurally, that is, automatically and unconsciously. When we talk in our mother tongue, we don't consciously assume the positions of our oral articulatory organs. We don't construct sentences by consciously applying the rules of grammar that we learned in elementary school. We are not aware of the phonological

rules that govern the stream of phonemes. We just talk. These are automatic behaviors, proceduralized motor and cognitive activities.

Neural Structures for Procedural Memory

The neural structures for the formation of PM are very complex, and only a simplified version will be presented below. The first characteristic of the PM system to be explained is called “chunking.” Simply speaking, chunking means that diverse, functionally related cortical neurons are connected and form a “chunk” while they pass through the basal ganglia structures and return to the cortical areas from which they originated. About 10,000 cortical neurons converge on a single striatal neuron, indicating that massive convergence of cortical information takes place through the striatum (Graybiel, 1998).

Second, there are two pathways in the system: the direct pathway and the indirect pathway. The neural connections of PM start from wide areas of the cortex. All areas of the cortex project to the striatum, which is the main structure of the basal ganglia. Striatal neurons relay the cortical input either to the internal or to the external segments of the globus pallidus. The signals relayed to the internal segment of the globus pallidus are sent directly to the thalamus and then to the cortex where the signal initially originated. On the other hand, the signals sent to the external segment of the globus pallidus go to the subthalamic nucleus, and then proceed to the internal segment of the globus pallidus. These signals travel from there to the thalamus and finally back to the cortex where they originated. The first pathway is called the direct, and the latter the indirect (Parent, 1996). These loops are presented in Figure 2.

Finally, the basal ganglia participate in three anatomically and functionally distinct circuits. These are the associative circuit, the motor circuit, and the limbic circuit. These originate from distinct parts of the cortex, travel through distinct parts of the striatum and the globus pallidus, project to segregated areas of the thalamus, and finally return to the distinct parts of the cortex from which they originated. Each of the circuits has its own direct and indirect pathways. However, they are interconnected by way of intrinsic circuits of the basal ganglia through which each distinct circuit can affect the others (Joel & Weiner, 1998). These circuits are schematically presented in Figure 3.

Evidence of the Basal Ganglia’s Involvement in Procedural Memory

Since the basal ganglia are located deep in the brain, conventional brain-scanning technologies such as PET (positron emission tomography) and fMRI (functional magnetic resonance imaging) cannot easily measure their activity. However, there is ample evidence regarding the question of the basal ganglia’s involvement in PM. When they are removed from animal brains, the animals lose the ability to perform motor routines such as walking or grooming. Parkinson’s disease stems from the degeneration of the direct pathway, and

Figure 2 The direct pathway and the indirect pathway

Figure 3 Split circuits

the patients cannot execute motor or cognitive routines. Linguistically speaking, they show agrammatism (omission of grammatical morphemes) and foreign accent syndrome (loss of phonological rules) (Carlson, 2001). Huntington's disease stems from the degeneration of the indirect pathway. As a result, the patients show perseveration, or overexecution of motor or cognitive behavior such as repeating the same words, phrases, or sentences (Purves, 1997; Fabbro, 1999).

Another body of data showing the basal ganglia's involvement in language arises from studies of basal ganglia lesions. If a monolingual person suffers a basal ganglia lesion, he or she develops the syndrome of voice disorders, foreign accent syndrome, perseveration, and agrammatism. Polyglots with basal ganglia lesions show damage in all of the languages they speak, but, generally, an L2 or foreign language tends to be less impaired than their mother tongue (Aglioti, Beltramello, Girardi, & Fabbro, 1996). The reason that the L2 is less damaged than the first language (L1) is probably that the L2 is less proceduralized than the L1.

Formation of Procedural Memory and Its Implication for SLA

Some researchers working in the area of SLA have claimed that L2 learners frequently learn co-occurring words as delexicalized chunks (Tannen, 1989; Sinclair, 1991). This may occur through the chunking mechanism of the basal ganglia. It is reasonable to hypothesize that routine expressions of the target language such as idioms (*by and large*), ritualized expressions such as greetings (*how are you?*), and other fixed expressions, clichés, or collocations may exploit the basal ganglia chunking mechanism.

Furthermore, the formation of the direct and indirect pathways may explain how we form and execute the rules of the grammar and phonology of the L2. When an L2 speaker tries to speak in the target language, she or he has to try to arrange words in grammatically and phonologically correct forms. Through numerous and repetitive target language inputs and the production of sentences, an L2 speaker slowly builds up stronger synapses among participating neurons in the cortex and basal ganglia which represent the rules of the target language through the direct pathway. The direct pathway is used to execute the acquired forms, and the indirect pathway is used to inhibit alternative forms. As the

speaker's proficiency in the L2 progresses, the direct pathway and indirect pathway may become efficient enough to select the correct program and inhibit incorrect programs.

Finally, the three circuits of the basal ganglia may have an important implication for L2 or foreign-language learning. Figure 3 shows that each circuit can function independently. The associative circuit is involved in cognitive processes, the motor circuit is involved in somato-sensory and somatic motor control and control of orientation and gaze, and the limbic loop is involved in emotional and visceral functions. However, each circuit is interconnected, and can affect the others. For example, considering the associative circuit's involvement with cognitive processes, it may play a role in deciding which items will be formed as motor routines in the motor circuit. This is even more likely considering the cortical areas from which this circuit originates, the dorso-lateral prefrontal cortex and orbito-frontal cortex. The latter is known to be involved in our social reasoning and cognition.

On the other hand, the limbic circuit may affect the formation of rules and routines in the other circuits in a different way. The limbic circuit originates from the anterior cingulate area, hippocampal cortex, entorhinal cortex, and superior and inferior temporal gyri. The hippocampus and entorhinal cortex have already been discussed above. These structures are involved in the formation of DM. This circuit may be the way by which our DM system affects the formation of PM. It is probably the case that almost all L2 learners have had the experience of making an error and realizing that they are making an error at the same time. The system that made the error is PM, while the DM system realizes that the error is being made. Through this self-monitoring, a kind of debugging may be taking place. Inaccurately formed PM is executed through the motor circuit, but the limbic circuit may debug the erroneous procedure by facilitating the transfer of information from the hippocampal system to the basal ganglia. The limbic circuit also passes through the ventral tegmental area instead of the globus pallidus. The ventral tegmental area is a source of a neurotransmitter, dopamine. Dopamine is involved in our emotional and motivational systems. Because of the involvement of the dopaminergic system, the limbic circuit may also affect the other circuits by giving motivational and emotional significance to each motor and cognitive routine and process. For example, if an L2 speaker successfully executes a sentence, the rules governing the sentence may be formed more strongly because the limbic circuit will give a positive response to the rule and the sentence. From this discussion, our stance on what is meant by "rules" should be evident. Rules, as instantiated in the brain, are created through repeated patterns and the building of circuits.

Summary and Conclusions

The above discussion can be summarized in Figure 4. Learning an L2 or foreign language consists of forming memories. We remember vocabulary, grammar rules, and phonological rules through DM, especially the semantic memory system that is subserved by the cortico-hippocampal loops. We automatize the rules of grammar and phonology by way of the PM system, subserved by the cortico-basal ganglia circuits. These two types of memories are modulated by the dopamine system.

This entry has outlined a perspective on adult SLA in which two neural learning mechanisms (the hippocampal declarative system and basal ganglia procedural system as modulated by the dopaminergic motivational system) are invoked to account for the development of the declarative knowledge and procedural knowledge that are necessary to speak an L2. The association of declarative and procedural learning with two systems in the brain may facilitate theorizing about how these processes function in SLA. Additionally, a neural view of these two types of knowledge provides detailed accounts of the actual physical (i.e., biological) mechanisms that subserve them. This detail will help generate

Figure 4 Neurobiological system of SLA

more articulated psychological and functional accounts. However, connections between the neural biology and SLA are, at this point, necessarily superficial. This is because, unlike strictly psychological/cognitive approaches where processes and mechanisms are inferred from behavior, in neuroscience, the mechanisms are physically instantiated. Thus, the explanations here are constrained by those biological instantiations. In this way, the biological constraints discipline theorizing about SLA processes.

Neurobiology and Motivation in Second Language Acquisition

ANDREA W. MATES

Motivation has long been seen as a critical variable in second language acquisition (SLA) in that it keeps a learner working on the long and difficult task of mastering a second language. Research in SLA has sought to better characterize the nature and impact of motivation on learning using a number of different methods. One more recent approach has been to take findings from neuroscience research and apply them to issues in SLA. Neuroscience concerns itself with understanding the organization and function of the nervous system which provides the biological basis for processing one's experiences of the world and directing one's actions within it. This entry will present an overview of this approach and discuss a proposed neurobiology of motivation in SLA.

One Neurobiological Approach to Studying Constructs in Applied Linguistics Research

Seeing discoveries in the biological sciences in relation to their import to questions in linguistics was popularized in Terrence Deacon's *Symbolic Species* (1998), which postulated a coevolution of language and the brain. In SLA research, this approach was presented in John Schumann's (1997) work *The Neurobiology of Affect in Language*. Subsequently, Schumann's research group produced a collaborative volume, *The Neurobiology of Learning: Perspectives from Second Language Acquisition* (Schumann et al., 2004). In that volume, the contributors propose neurobiological systems that could be involved in important SLA constructs such as aptitude, motivation, procedural and declarative memory, memory consolidation, and attention.

Nancy Jones examines the neurobiological research on memory consolidation in that volume (Schumann et al., 2004) and links it to SLA topics such as the bilingual lexicon—how words from more than one language are stored; individual differences—dimensions along which individuals may vary such as aptitude or motivation; and fossilization—a stage of second language use where fluency is developed and improvement is rare even in a target language immersion environment. Instead, grammatical errors and non-native phonology persist and are “fossilized.” With regard to the bilingual lexicon, Jones reviews the Hebbian model of language (HML) proposed by Friedemann Pulvermüller (1999). Pulvermüller presented research suggesting that lexical items are not stored in specific neurons (cells in the brain) or in a network of neurons in a particular part of the brain. Instead, taking Hebb's theory that neurons which are activated at the same time begin to develop an association that over time can functionally become a single unit or cell assembly (Hebb, 1949), Pulvermüller suggested that lexical items are stored across networks of cells widely distributed across brain regions. Implied is the idea that different lexical items with similar properties—form, meaning, usage—may have that part of their network in common. Using different brain recording methods, Pulvermüller's research demonstrated how words with a predominant movement component appear to be connected to motor regions of the brain while words with a greater visual component showed involvement with vision

processing regions. Jones's discussion of the HML is but one part of a much larger hypothesis she forms about the neurobiology of memory consolidation and its role in managing a bilingual lexicon; however, this short description provides a taste of how neuroscience studies are being applied to questions in SLA.

Schuchert takes the construct of attention in learning and examines the neurobiological processes that may support it (Schumann et al., 2004). In doing so, she raises a challenge frequently encountered while trying to link neurobiology and SLA processes—a mismatch between the psychological construct and the underlying neurobiology. A single psychological construct frequently does not have a corresponding brain module as its biological basis.

Schuchert thus begins by describing how attention has been historically understood. It has been frequently treated as a unitary concept, something like “voluntary control over automatic brain processes (Schumann et al., 2004, citing Posner & Petersen, 1990, p. 144). However, the research community actually tested it using different overlapping definitions and subcategories. As a result, she concludes that attention is likely to be a cultural construct without a single, dedicated underlying neurobiological substrate. In order to give a neurobiological account of attention, she must describe a number of systems that are engaged in the process of perceiving the environment, acting on self-directed goals and responding to external stimuli. These include a number of different brain regions and functions including the dorsolateral prefrontal cortex, the parietal cortex, frontal-parietal connections, the anterior cingulate, and the intrinsic tuning of neurons to particular stimuli. Schuchert then argues that this neurobiological account of attention accounts for noticing as a strategy for correcting fossilization in adult SLA.

The strength of a synthetic approach to tying neuroscience research to problems in SLA is that it forces just such a reexamination of psychological terms which are often in a state of redefinition or subcategorization. It also allows for a complex, nonlinear discussion of mechanism and causality. Experimental design calls for controlling variables so that something meaningful can be said about the relationship between the independent and dependent variable. This is an important part of the scientific method. However, as one probes deeper into the questions concerning SLA and the brain, one must acknowledge that the brain itself does not work linearly (Lee, Mikesell, Joaquin, Mates, & Schumann, 2009). Instead, we frequently find that different regions of the brain share information back and forth in a feedback loop. The neurobiological approach presented here is one in which the researchers step back from the results of rigorous experimentation in both neuroscience and SLA and hypothesize about connections between the two.

A Neurochemical Approach to Affiliation and Motivation

The previously described approach has been most frequently applied to motivation in SLA. Schumann took it up in his 1997 book on affect in language, and then elaborated on both the neurobiology and its applications in subsequent publications, either on his own or with his students (Lee et al., 2009; Schumann, 2001; Schumann et al., 2004).

One thought on a neurobiological substrate for motivation sees adult motivational systems as reuses of some systems that support infant–caregiver bonding, also known as affiliation. Infants are born with what has been described as an “interactional instinct” (Lee et al., 2009) in the sense that they have and devote much of their resources to interacting with the people around them, particularly their mothers. While infants are limited in their cognitive and motor abilities, they can track eye gaze, head position, vocalizations, and facial expressions, which allows them to establish or maintain the attention of a caregiver. Lee et al. (2009) argue that this phenomenon is supported by the biochemical rewards infants receive when they pursue and achieve affiliative goals.

In their earliest experiences, when infants are fed or gently held, their nervous systems quiet down in a process facilitated by so called consummatory rewards (Lee et al., 2009 citing Depue & Morrone-Strupinsky, 2005). Consummatory rewards are experienced as opiates released in the hypothalamus reach a number of different regions including the amygdala, which is part of the emotional response system. In addition to experiencing good feelings from being fed or held, infants can remember the contexts in which those feelings were achieved. Four regions of the brain encode the context and feed that information to medium spiny neurons in the nucleus accumbens shell, a region which will be discussed further below. The four regions are the hippocampus, which encodes the spatial, contextual features of the environment; the basolateral amygdala and the extended amygdala, which encode the conditions for reward; and the medial orbital frontal cortex, which encodes the reward expectancy through a high-level synthesis of all these lower levels of information. Memories of rewarding situations develop through long-term potentiation (LTP) on the dendrites of the medium spiny neurons where these connections end.

Having these memories of comforting or sated experiences using the limited motor control they do have, infants are able to pursue courses of action that will likely produce similar results. For example, a hungry infant can remember being full after her mother comes and nurses her and that crying draws maternal attention. Or a distressed infant can remember that being held or played with is enjoyable and that cooing or sustaining mutual eye gaze may draw an adult into that kind of interaction. In the pursuit of their goals, infants receive “rewards along the way” called appetitive rewards as they encounter cues that the desired goal is closer (Lee et al., 2009, citing Depue & Morrone-Strupinsky, 2005). Distressed infants may begin experiencing appetitive rewards when they observe a caregiver turning toward them, smiling, and extending arms to pick them up. Appetitive rewards are mediated by dopamine produced in the ventral tegmental area (VTA) of the brain stem. Dopamine released by the VTA travels to the same previously mentioned medium spiny neurons in the nucleus accumbens shell. The nucleus accumbens shell is a subcortical structure that has been frequently the focus of research in the areas of reward, pleasure and addiction.

In adults, these same structures and processes are at work even though there are fewer dopamine and opiate receptors (Lee et al., 2009). While it may take a greater stimulus to provide the same amount of reward, adults with mature nervous systems can find many more stimuli to be rewarding. Food and physical touch may still be rewarding, but with more developed cognitive and motor abilities the array and complexity of goals that can be sought and achieved are manyfold greater. Seeking employment, for example, is a multistep process with many opportunities for action and occasions for set backs. Revising a resume, submitting a resume to a particular employer, securing an interview—these are all parts of the process. As each milestone is passed a person may experience consummatory rewards from achieving the milestone, while also receiving appetitive rewards from the feedback that the ultimate goal, securing employment, is one step closer. These rewards are mediated by the neurochemical processes described above and propel goal-seeking behavior.

Stimulus Appraisal as the Underlying Mechanism for Motivation in SLA

In addition to neurochemical rewards which influence goal-oriented behavior, other parts of the nervous system play an important role in determining how to proceed. Here, stimulus appraisal will be discussed as the underlying mechanism for motivation, and a neurobiology of stimulus appraisal will be presented and integrated with the previous section.

In attempting to connect the impact of emotion on SLA research concerns, Schumann (1997) turned to a body of work from the 1980s on the topic of stimulus appraisals and drew heavily from Scherer's model (1984). In this model, individuals conduct checks across five categories as they encounter stimuli, and these checks in turn inform emotional responses. The five categories on which a stimulus is appraised are (a) novelty; (b) pleasantness; (c) the extent to which it may contribute to one's goals or needs; (d) how the stimulus corresponds with one's coping potential—both in the sense of the ability to actively respond and also to manage any consequences beyond one's control; and (e) how the stimulus may affect our self- and social image (Schumann, 1997, citing Scherer, 1984). Different kinds of appraisals appeared to lead to different emotional responses such as joy, sadness, fear, anger, disgust, and so forth. But generally, positive appraisals allow for approach while negative appraisals are likely to induce retreat. Schumann saw the link between stimulus appraisal and language learning in Scherer's claim that positive stimulus appraisals are the basis for sustained deep learning, the kind of learning that isn't inevitable due to biology or intense social pressure but which must be actively pursued over an extended length of time.

The neural basis for stimulus appraisal initially proposed in Schumann (1997) focused on the contributions of the amygdala, orbital frontal cortex, and the body proper. The amygdala is located in the medial temporal lobes behind the ears and is part of the limbic system. It has been the subject of intense scrutiny, initially for its role in fear responses (LeDoux, Cicchetti, Xagoraris, & Romanski, 1990; Davis, 1992) and now for its broader roles in emotional and social responses (Amaral, 2003). One characteristic of the amygdala is that it receives two copies of sensory information: one directly from the thalamus and one indirectly from thalamic projections that pass through the regions of the cortex which process that kind of sensation—vision, audition, taste, touch, and so forth. The direct copy of sensory information from the thalamus allows the amygdala to make a very quick and crude initial assessment of the potential danger a stimulus might pose. The indirect copy has been first processed by the brain and provides a more nuanced assessment that may or may not agree with the initial assessment. That shadow of a coiled thing in the bushes may first appear to be a snake ready to strike warranting a quick fear response. However, the slightly delayed assessment from the cortex may show that the coil is merely a pile of discarded rope warranting little attention. With the indirect copy, the amygdala can attach a fine-tuned emotional value to stimuli and send that back to the cortex, thalamus, and other regions of the brain such as the previously mentioned nucleus accumbens shell and hypothalamus.

The frontal cortex is a late-developing part of the brain and has been called the executive for its role in planning and control of impulses from other parts of the brain. The orbital frontal cortex, a region just above the eyes, has been connected with many different functions, many of which are related to social and emotional responses. In patients with damage to the orbital frontal cortex, a deficit in emotional processing results in socially inappropriate behavior and an inability to follow through with plans. As mentioned in the previous section, the medial orbital frontal cortex on the surface between the two hemispheres of the brain acts as a high-level synthesizer of the contexts for reward by taking information from both the amygdala and the hippocampus.

The body proper refers to the peripheral nervous system outside of the brain and spinal cord. These include the nerves that control the musculoskeletal system for movement as well as the autonomic nervous system that controls arousal. The autonomic nervous system controls pupil dilation, heart rate, and perspiration in response to stimuli requiring fight, flight, freeze or engagement responses (Lee et al., 2009; Mates & Joaquin, in press). The autonomic nervous system in particular has connections with the orbital frontal cortex and amygdala via the brain stem. This interaction between the body and the brain is the

biological basis for “gut feelings” and thus acts as another piece of the stimulus appraisal system.

In SLA, an appraisal made through the interaction between these three systems may lead a learner to seek a conversation partner to practice with. However, during the first meeting, the learner may not achieve the goals they had for that encounter and experience both a lack of consummatory and appetitive rewards. After several disappointing meetings, they may reappraise the situation and decide to withdraw from that activity. Schumann characterized this appraising and reappraising as “learning as foraging” (2001).

Criticism

Two criticisms of this approach to questions in SLA are that the work is fundamentally speculative and that it does not produce or leave in its wake a particular research agenda or methodology. The two criticisms are related and epistemological in nature, the question being how we can know whether the proposed neurobiological mechanisms really play those particular roles in SLA. The simple answer is that at this point there is no substantive proof, but some of the connections drawn could be tested with modern experimental methods, and various contributors in Schumann et al. (2004) have proposed brain-imaging research studies. Additionally, while speculative in regards to brain mechanisms for SLA, the neuroscientific research reviewed is real. And this biological reality, while complex and nonlinear, can help one to get around the sticky problem of constantly defining and redefining psychological terms.

Conclusion

Motivation in the course of SLA is supported by systems of neurochemical reward and the neurobiology of stimulus appraisal. Dopamine provides appetitive rewards helping learners feel that they are closer to achieving their goals. Opiates provide consummatory rewards allowing learners to “rest on their laurels” for a while when they achieve particular milestones. The amygdala, orbital frontal cortex, and the body proper work together to appraise and reappraise the environment so that learners can decide whether and how to continue the language-learning process. All told, stimulus appraisal forms the antecedent to motivation.

Neurolinguistic and Cognitive Aspects of Interpreting

ROBIN SETTON

Introduction

Interpreting looks at first sight like rapid language transfer, a kind of instant translation relying on exceptional linguistic proficiency, but there is direct and indirect evidence of abundant supporting cognitive activity. Consecutive interpreters do not use shorthand but spare, personalized notes that cannot be read by others without explanation (Seleskovitch, 1975); not all bilinguals or expert translators can be trained in simultaneous interpreting (SI), as early recruiters discovered at the Nuremberg trials (Gaiba, 1998); transcript analysis shows extensive use of extralinguistic knowledge and context (Setton, 1999); and neuroimaging has shown increasing involvement of both brain hemispheres with expertise (Gran, 1990).

SI, in particular, soon aroused the curiosity of psychologists, and some skepticism among linguists and translators, since it seemed to challenge both existing models of speech processing and assumptions about the translation process. How do interpreters—apparently to the daily satisfaction of thousands of users—divide their attention between listening and speaking, or convert a self-contained coherent discourse from one language into another, through asymmetric syntax and semantics, with a delay of only a few seconds?

Since then, interpreting has been studied at three levels: social and relational, as mediated communication; cognitive, as a specific configuration of mental operations; and neural, in search of the specific correlates of this expert activity in the brain.

With new and more flexible models of the mind's potential from cognitive science, and recent advances in brain research, a plausible cognitive and neurolinguistic picture is gradually taking shape. Interpreting is a live, situated, real-time activity. While this poses major methodological challenges for research, it also provides a clue to its feasibility: Given certain minimal working conditions, the situated, contextualized nature of the task provides cognitive opportunities that can be leveraged in support of the apparent linguistic feat. Neurolinguistic research has already provided some evidence of the gradual configuration of the bilingual brain for this task with increasing expertise.

New Cognitive Models

The birth of modern conference interpreting coincided with the beginnings of cognitive science, which has since fueled interpreting research with models and findings about memory, attention, communication, and the bilingual brain. The “black box” has been probed through both experiment and observation, from retrospective interviews through transcript analysis to neuroimaging. Early work by psycholinguists and interpreters studied constraints like noise or delivery speed (Gerver, 1969, 1974), patterns of linguistic restructuring (Goldman-Eisler, 1972), or variations in the lag or “ear-voice span” (from 2 seconds to 11 seconds; Lederer, 1981), and proposed process models.

Through the 1960s and 1970s, early models of interpreting took their cue from code-based, computational, usually serial, information-processing models of communication (Shannon & Weaver, 1949), with yes/no decision points, feedback loops, box-like memory buffers, phrase-structure constrained sentence processing (Goldman-Eisler, 1972), and switching between competing attention channels. It was suggested, for example, that simultaneous interpreters must speak during pauses in the input, until recordings showed that the two speech streams overlap about 70% of the time (Čeřková, 1985; Chernov, 1992).

Today, more flexible models of memory, attention, and discourse processing, and a new understanding of the role of context and inference in verbal communication, are helping to show how interpreting expertise might be configured in the brain. Descriptive linguistics—the study of *langue*—has played a minor role, despite ongoing discussion about the effect of typological differences between source and target languages.

Discourse Processing and Memory

SI does not seem feasible as a purely linguistic operation in which successive chunks of speech would be retained in verbal form long enough for translation and comparison. First, this would entail two parallel processes of parsing and word retrieval, plus translation, coordination, and monitoring output. Second, in the current model of working memory (Baddeley, 1986), *verbal* traces of recent speech in the “phonological loop” can only be maintained by subvocal articulation, and would therefore be suppressed by concurrent vocalization, that is, talking while listening.

Since early seminal psycholinguistic studies confirmed that listeners quickly process speech into a conceptual format (Sachs, 1967), it has become clear that speech comprehension cannot rely entirely on decoding and parsing, but must be a parallel and incremental process in which words and other clues activate knowledge that helps to resolve ambiguities, restore or reconstruct elliptical or ungrammatical forms, and make constructive predictions, all as the utterance unfolds (Altman & Steedman, 1988; Carston, 2002). Indeed these three tricks of human speech processing turn out to be key challenges for machine interpretation (Kitano, 1993).

This model of verbal communication, in which inference supplements and interacts with decoded language, followed the exposure of the indeterminacy of language by the “ordinary language philosophers” (such as Austin, Searle, and the later Wittgenstein), and has been developed, after Grice, in the pragmatic turn in linguistics, notably relevance theory (Sperber & Wilson, 1986/1995). The massive use of context is made more plausible by “spreading activation” models of the brain as a network that can be trained with expertise to deliver the most relevant input for a specific task like interpreting (Shreve & Diamond, 1997). Discourse processing improves with increased availability of relevant knowledge schemas, and of procedures like analogy or pattern matching. There is evidence that expert interpreters rely more on context than do novices, less on linguistic transfer (Ilic, 1989), and show superior domain-specific (but not general) working memory (Liu, Schallert, & Carroll, 2004). “Memory” is a distributed function that uses multiple formats—analogue, visual, and episodic, as well as linguistic—allowing processing economies through task-specific cognitive expertise. “Long-term working memory” (Ericsson & Kintsch, 1995) or “embedded-process” models (Cowan, 1999) now offer more flexible accounts of the management of memory and attention.

Attentional Resources and Cognitive Load

Without training, speaking while listening will naturally result in attentional conflict. Novices who have not yet learned to coordinate the two streams (Pinter, 1969), or gained sufficient cognitive control to merge input and output in a single cognitive representation,

will experience SI as “multitasking,” a difficult balance between listening and analysis, production, and self-monitoring, and thus divided attention and higher cognitive load, and will have trouble seamlessly combining the hearing, analyzing, and noting that are needed for full professional consecutive interpreting. “Effort models” of interpreting (Gile, 1997) highlight this cognitive management problem. Experts may learn to mask these conflicts, but may also learn to allocate attention to multiple processes under different degrees of focus, relieved by partial automation of some procedures, and by more easily mobilized, “overlearned” language resources for production.

Coordination and control in the use of two languages must also take energy. According to Paradis (1994, p. 321), “a more complex regulation system is needed [for interpreting] than for regular speech”: The languages can be independently activated, but SI must be particularly taxing since first and second language (L1 and L2) must be activated at the same time but not to the same extent, comprehension and production requiring different activation levels. Resisting linguistic interference—the partial suppression of the interpreter’s other language(s)—takes a significant effort, especially between cognate languages. Production takes more energy than comprehension, since it involves the voluntary self-activation of memory traces, and is especially demanding when interpreting into an acquired (“B”) language, as neurological evidence seems to confirm (Rinne et al., 2000; Tommola, Laine, Sunnari, & Rinne, 2000).

“Free” versus “Literal” Translation: Two Routes?

Translation theorists traditionally contrast two kinds of translation: “literal” (or “sign-oriented”), showing a recognizable item-by-item surface correspondence between words, expressions, and syntactic structures in the source and target texts, and “free” (or “meaning-based,” “sense-oriented”), with correspondences apparent more at the conceptual than at the linguistic level. In speech comprehension theory, this is reflected in the contrast between bottom-up and top-down processing, and in machine translation, between “transfer” and “interlingua” approaches. Interpreter trainers and researchers have long debated the respective role (and desirability) of reformulation and “transcoding.” Two distinct translation “routes” are hard to distinguish reliably in the product, but intuitions about them have persisted in theories of interpreting. Gran speaks of a widespread feeling among interpreters of a contrast between “pleasant (sense-based) vs. forced (literal-based) interpreting, both of which are necessary” (1990, pp. 97–9). The interpretive theory of translation (ITT), developed at the ESIT training school in Paris, famously insists on conceptual understanding and “deverbalization”—reformulation independently of the source words and structure—as the preferred method for good translation or interpreting, with “transcoding” only an occasional and inevitable local complement. However, direct linguistic conversion is also necessary, even with the cognitive support from schemas and procedures that comes with expertise, since each new speech contains some new material, and stock equivalents are needed for formulas, set expressions, technical terms, and, sometimes, words that cannot yet be integrated into conceptual processing (Lederer, 1981). Professional interpreters demand contextual background for their assignments, but usually also prepare glossaries, even if only for self-priming (Setton, 2003).

The relationship between these two kinds of processing has been directly addressed in a neuroscience perspective. Paradis’ hypothesis (1994, 2000) is that “context-independent sentence grammar is neuro-functionally separate from pragmatics,” and that interpreters “rely on one or the other depending on the syntactic or pragmatic characteristics of the utterance” (1994, pp. 328–9), in a kind of cooperative alternation, according to circumstances, between linguistic work in the left hemisphere and “pragmatic” processing in the right. Interpreting should thus engage both brain hemispheres, but to different degrees

at different times: the left (in right-handed individuals) for primary linguistic decoding (phonological, morphological, syntactic, lexical), the right for the interpretation of implicit meaning (inference from knowledge, situation, affective prosody, and other paralinguistic features).

This dichotomy seems essentially human. Machine interpretation implements two much more basic routes: syntactic spadework versus lexical retrieval (of “canned phrases”). Indeed, even with knowledge banks and contextual input it is still difficult to see how artificial systems could achieve the higher, holistic processing needed to negotiate pragmatic values like relevance and appropriateness.

Neurolinguistic Research

Since the 1990s, neurologists and interpreters have teamed up to explore the neural correlates of interpreting, building on spectacular advances in neuroimaging and the cerebral localization (or distribution) of linguistic and cognitive functions, particularly in the bilingual brain.

In that time neuroscientists have identified regions of the brain specialized in most of the component functions assumed to be most involved in interpreting, such as the phonological loop in working memory (Broca’s area), episodic and semantic memory (laid down in the hippocampus, encoded throughout the cortex), procedural memory (putamen), attention, and “executive functions” (frontal lobes), and even finer distinctions such as centers for stimulus integration, planning, and decision making, or “bestowing meaning on perceptions” (Carter, 1998). However, neuroscientists agree that “there is no simple one-to-one mapping between brain areas and cognitive functions” and that “different parts of the brain probably are specialized for different functions, but most of those functions are likely to be shared *sub-components* for computation, not complete systems for single-handedly solving complex cognitive tasks” (Marcus, 2004, pp. 129, 133; original italics).

Memory and language are two examples. It now seems that “there is no rigid dividing line between memory and thought” (Carter, 1988, p. 188). “Neural substrates for memory are found not just in one location in the brain, but spread throughout . . . in the hippocampus . . . but also the cortex, amygdala and in a variety of visual and motor areas” (Marcus, 2004, p. 102). Similarly, while language processing is centered on Broca’s and Wernicke’s regions, our knowledge about words, “rather than being confined to a single box . . . may be scattered across different regions of the brain [visual, motor, auditory]” (2004, p. 129). Scans show that activities traditionally lumped together as “linguistic”—hearing a word versus considering what other words it relates to, or counting its syllables versus thinking about what it means—activate quite different areas. “When you see a word, you may see it as a word—that is, as a component of language—or it may act as a trigger for the concepts it represents. In each case a different part of the brain comes into play” (Carter, 1998, p. 148).

Complex cognitive-linguistic processes, such as “predicting, juggling concepts, selecting thoughts for attention and ignoring others, binding perceptual units into a unified whole, and most important, endowing those perceptions with meaning” (Carter, 1998, pp. 182–3), have been associated notably with the supplementary motor area (SMA, or “pre-motor cortex”), which seems to be involved in *pre-production/formulation*. The insula is believed to integrate stimuli from several different sources, perhaps including different languages (1998, pp. 182–3), while control and choice of language in bilinguals have been associated with the left caudate nucleus (Crinion et al., 2006). *Automatization* of tasks is seen in scans of a subject alternating between choosing new words and repeating practiced, learned sequences (Crinion et al., 2006, p. 196). *Attention* turns out to be highly complex, involving

arousal, orientation, and focus, all associated with different brain areas. Neurological evidence seems to vindicate interpreter trainers' insistence on the difference between mere hearing and active listening.

Even the ability to "meta-represent" others' beliefs and intentions ("theory of mind," impaired notably in autism), which is key to empathy and speaker (or listener) identification, has been associated with a neural substrate (in the left premedial prefrontal cortex; Frith, 1997; Crinion et al., 2006), while the recently discovered "mirror neurons" promise future insights.

While it appears increasingly difficult to isolate "memory," "attention," or "language processing," evidence of increased hemispheric lateralization in interpreters suggests activity which systematically integrates functions well beyond the domain of language *per se*.

The Bilingual Brain

Inferences about linguistic-functional organization in bi- and multilinguals have come mostly from evidence of selective impairment in aphasic patients. However, as the interaction between language and other cognitive functions begins to look more complex, the classic models inferring language configuration from performance on certain simple tests and the circumstances of L1 and L2 acquisition (e.g., the "compound" vs. "coordinate" bilingual distinction; Weinreich, 1953, pp. 9–11; Ervin & Osgood, 1954) are being reassessed in a lively debate that is beyond the scope of this entry. Such accounts may indeed turn out to be too static and unable to account for some reconfiguration and enhancement of language activation patterns that might be acquired with task-specific expertise. Paradis (2000) postulates four systems, one each for comprehension and production in each language, which for translation must be in a specific state of activation or inhibition to minimize interference, with two possible "routes": via conceptual mediation or direct linguistic correspondence.

Neural Correlates of Interpreting

Neurological research on interpreting has focused on hemispheric lateralization, or has attempted to map task-specific activation patterns. The left brain (in particular Broca's area) is believed to be responsible for key language functions (decoding, verbal memory, articulation) and most analytical and propositional information processing, while the right brain is more specialized for analogical and holistic processing, orientation (space memory, form recognition), face recognition, emotion, and diffuse attention, but also some acoustic, phonetic, and prosodic dimensions of speech such as pitch (Fabbro, 1991). Language processing is already known to be more lateralized (symmetrical) in women, and in (especially early) bilinguals (Vaid & Lambert, 1979; Sussman, Franklin, & Simon, 1982), while late-acquired (post-puberty) L2 use seems to rely more on right-brain processing.

Acquisition of new cognitive skills is known to reconfigure brain functions (Raichle, 1998; Cabeza & Nyberg, 2000), and task type and ability have been shown to influence the level and locus of cerebral activation (Haier et al., 1988). In particular, ideational activity (conscious manipulation of continuous deliberative thought, as in interpreting) shows different lateralization patterns from nondirected vocalized tasks (like shadowing).

Against this background of knowledge about the bilingual brain and the effects of skill acquisition, the next step—an experimental design challenge—is to isolate and capture the task-specific conditions of interpreting. This is still beset by many obstacles. Cumber-some equipment and procedures still prevent imaging of the task in real conditions, and studies have been criticized for poor ecological validity, task choice, experimental design, or statistical limitations (Green, 1986, p. 332; Pöschhacker, 2004, p. 114). Electroencephalography (EEG), positron emission tomography (PET), and functional magnetic resonance

imaging (fMRI) studies have contrasted interpreting by image “subtraction” with less demanding tasks like shadowing or speaking while listening. On some issues, such as ear (or hemisphere) preference for L1 or L2, the evidence is still inconclusive or contradictory, but other findings show some consistent patterns.

1. Novices detected syntactic errors in translated sentences better than professionals, but professionals detected semantic errors better (Ilic, 1989; Fabbro & Gran, 1994).
2. More hemispheric lateralization was seen in interpreting than in shadowing (Green, Schweda-Nicholson, Vaid, White, & Steiner, 1994).
3. More lateralization was found during interpreting with increasing expertise, specifically “a gradual shift in cerebral lateralization during interpreter training, from left-hemisphere dominance in Y1 [year 1] students through to balanced cerebral representation in advanced students and significant lateralization to the right hemisphere in experienced interpreters” (Gran, 1990, p. 12).
4. Left supplementary motor area (SMA; pre-motor cortex) activation was seen in SI, but not in shadowing (Rinne et al., 2000).
5. Significantly increased gray matter density in Brodmann area (BA) 46, specialized in selective language activation or suppression, has been measured in professional interpreters (Krick, Reith, Behrent, & Franceschini, 2005).

Bridging the Levels of Analysis

Clearer findings might be expected with more realistic simulation of the task variable, but the challenge remains of bridging the different levels of analysis that see interpreting as neural activity, as a configuration of cognitive functions, as linguistic performance data, or as purposeful mediation in social communication. It will no doubt be some time before we can match neural maps to behaviors and productions; to other forms of data, such as subjects’ reported peaks of effort or difficulty; or to theoretical functional configurations. One promising research strategy is “triangulation,” mixing and matching such different methods as transcript analysis and subjects’ retrospective think-aloud protocols (TAPs). Shreve and Diamond (1997) suggest that peaks of effortful processing might be reported in TAPs, but that neuroimaging would be more effective in spotting psycho-physiological changes reflecting, for example, responses to novel stimuli (new vs. old information) which could be inserted or identified in experimental texts.

Conclusion

Cognitive scientists and practicing interpreters have both contributed their perspectives to the study of interpreting, the former providing models and research methodology, the latter drawing attention to aspects that help in an understanding of interpreting as a holistic cognitive and communicative task, such as the peculiar features of situated oral communication, and the crucial role of the live context. Cognitive modeling and neuroscience made great strides in the 1990s—the “decade of the brain”—in which matching neural accounts were proposed for models of memory (Baddeley, 2004) or discourse processing (Kintsch, 1998). Memory and attention, once conceived of as boxes and channels, are now seen as complex and distributed, while other functions, though locally specialized, have been increasingly seen to work together and in parallel. Connectionist, brain-like, trainable models now seem better able to express both the process of acquiring expertise and the combination of top-down and bottom-up processing needed to deal with the speed and variability of conference speech.

The key to modeling the cognitive processes of interpreting now seems to lie in recognizing a highly task-specific acquired expertise, based on building and selectively activating relevant knowledge schemas and language resources, and partial automation of some processes to free up capacity for the most immediate, unpredictable aspects of the discourse. Cognitive load would vary with the efforts needed for selective language activation and inhibition (to resist interference), and to access relevant contexts. Experts should gradually develop relevant and easily activated cognitive-linguistic representations, and procedures in implicit memory, to supplement bottom-up processing and thus save effort for polishing the product. Experts thus get more from the signal, use more cues, and activate more, so that the activation input returned to working memory is richer and more complex (Shreve & Diamond, 1997). Increased hemispheric lateralization with expertise may reflect more holistic processing, making more use of extralinguistic information, of analogies with patterns and schemas from experience, and of paralinguistic, prosodic, and visual cues.

In summary, it seems reasonable to assume significant cognitive specificity of the interpreting task, as distinct from the automatic linguistic transfer of short and decontextualized items in controlled conditions that may have informed some generic models of language processing. This specificity applies not only to SI, which has attracted the most attention, but also to consecutive interpreting, in which the speed and density of the material translated, if accurate and idiomatic, imply significant task-directed conceptualization and knowledge mobilization.

New Literacies of Online Reading Comprehension

DONALD J. LEU, HEIDI EVERETT-CACOPARDO,
LISA ZAWILINSKI, J. GREG MCVERRY, AND W. IAN O'BYRNE

Literacy as Deixis

Literacy has become deictic (Leu, 2000); the meaning of literacy is rapidly changing as new technologies for literacy continually appear and new social practices of literacy quickly emerge. Historically, literacy has always changed. Today, however, new technologies and new social practices rapidly and repeatedly redefine what it once meant, in a simpler world, to be able to read, write, and communicate effectively.

To be literate today often means being able to use some combination of texting, Facebook, Google, foursquare, Google docs, Skype, Chrome, iMovie, Contribute, or any of thousands of mobile “apps.” To be literate tomorrow will be defined by even newer technologies that have yet to appear and even newer social practices that we will create to meet unanticipated needs. Literacy has become deictic, indeed.

An important source of this change is the Internet. The Internet is the most efficient system in the history of civilization for delivering new technologies to read, write, and communicate (Lankshear & Knobel, 2006). It is also an amazingly efficient system for rapidly disseminating new social practices for the use of these technologies. The growth rate of Internet connectivity has been exponential. Nearly 30% of the world’s population (in 2011, 1.9 billion individuals) use the Internet (*Internet World Stats: Usage and Population Statistics*, 2011). At the current pace, more than half of the world’s population will be online by 2017, and most of the world will be online by 2025. Never in the history of civilization have we seen a new technology adopted by so many, in so many different places, in such a short period of time.

As a result, the deictic nature of literacy will quickly accelerate as even more individuals come online, creating even more technologies for literacy and evolving even more social practices, rapidly disseminating both over the Internet. The changing nature of literacy will be limited only by the capacity of humans to adapt to even newer literacies.

A Central Question: How Do We Conceptualize Literacy When It Has Become a Deictic Construct?

How should we conceptualize literacy when it is seemingly ephemeral? The answer is central to the study of literacy and, since literacy defines us, is central to our understanding of who we are. How we conceptualize literacy is also important to preparing each new generation for the literacies that will define their future. Thus, literacy defines both who we are and who we shall become. This is the central challenge to literacy in a deictic world generated by the Internet. As a result, it becomes essential to develop a precise definition for this construct, especially if we hope to study it systematically and improve both equity and access to literacy.

DOI: 10.1002/9781405198431.wbeal0865

That literacy is changing can be seen in the fact that many scholars have recently sought to describe these changes (e.g., New London Group, 1996; Kress, 2003; Street, 2003; Lankshear & Knobel, 2006; Gee, 2007). Each attempted to describe an important aspect of the changing nature of literacy in a world in which many new social practices and new technologies are altering the traditional terrain of literacy, expanding it in important ways.

Some use the term *new literacies* to capture the new social practices of literacy that are emerging (Street, 2003). Rather than seeing new social practices emerging from new technologies, they tend to see new technologies emerging from new social practices. Others use the term to describe important new strategies and dispositions that are essential for online reading comprehension, learning, and communication (Henry, 2006; International Reading Association, 2009). Still others see new literacies as new discourses (Gee, 2007) or new semiotic contexts (Kress, 2003). Still others see literacy as differentiating into multiliteracies (New London Group, 1996) or multimodal contexts (Hull & Schultz, 2002), and some see a construct that juxtaposes several of these orientations (Lankshear & Knobel, 2006). When one includes terms such as *ICT literacy* (International ICT Literacy Panel, 2002) or *informational literacy* (Kuiper & Volman, 2008), the construct of new literacies becomes even broader. Indeed, just what new literacies means today is confusing; it depends on who uses it.

There is an opportunity to benefit from the richness of these different perspectives. Recognizing that changes are taking place at many levels and dissatisfied with these isolated attempts to capture those changes, some are beginning a collaborative approach to theory building (see Coiro, Knobel, Lankshear, & Leu, 2008), one that takes advantage of the power of multiple perspectives (Labbo & Reinking, 1999). This approach assumes that the best solutions result from collaborative groups who bring diverse, multiple perspectives to problems (Page, 2007). The approach is based on *New Literacies* theory (Coiro et al., 2008; International Reading Association, 2009). New Literacies theory takes an open-source approach, inviting everyone who studies the Internet's impact to contribute to theory development and to benefit from others' contributions.

A Dual-Level Theory of New Literacies

New Literacies theory (Leu, O'Byrne, Zawilinski, McVerry, & Everett-Cacopardo, 2009) works on two levels: uppercase (New Literacies) and lowercase (new literacies). *New Literacies*, as the broader concept, benefits from work taking place in the multiple, lowercase dimensions of *new literacies*. Lowercase theories carefully explore either a specific area of new literacies, such as the social communicative transactions occurring with text messaging (e.g., Lewis & Fabos, 2005), or a focused disciplinary base, such as the semiotics of multimodality in online media (e.g., Kress, 2003). Common findings across multiple perspectives are then included in the broader New Literacies theory.

This approach permits everyone to fully explore their unique, lowercase perspective of new literacies, while everyone also benefits from expanding their understanding of other, lowercase, new literacies perspectives. By assuming change in the model, everyone is open to a continuously changing definition of literacy, based on the most recent data that emerge consistently, across multiple perspectives, disciplines, and research traditions. Moreover, areas in which alternative findings emerge are identified, enabling each to be studied, again from multiple perspectives. From this process, common patterns emerge and are included in a larger, common, New Literacies theory.

What currently defines this larger theory of New Literacies? A recent review (Coiro et al., 2008) concludes that most lowercase new literacies perspectives share four elements:

1. New Literacies include the new skills, strategies, dispositions, and social practices that are required by new technologies for information and communication;

2. New Literacies are central to full participation in a global community;
3. New Literacies regularly change as their defining technologies and social practices change; and
4. New Literacies are multifaceted and our understanding of them benefits from multiple points of view.

Additional, common, elements will emerge as more work is completed at lowercase levels, informing all scholars who seek to understand the changes taking place to literacy.

The New Literacies of Online Reading Comprehension

The new literacies of online reading comprehension (Leu et al., 2009) is one example of a lowercase theory. This perspective frames online reading comprehension as a process of problem-based inquiry involving the new skills, strategies, dispositions, and social practices that take place as we use the Internet to solve problems and answer questions. At least five processing practices occur during online reading comprehension:

1. reading to identify important questions,
2. reading to locate information,
3. reading to critically evaluate information,
4. reading to synthesize online information, and
5. reading and writing to communicate online information.

Within these five areas reside the skills, strategies, and dispositions that are distinctive to online reading comprehension as well as others that are also important for offline reading comprehension.

Reading to Identify Important Questions

We read on the Internet to solve problems and answer questions. How a problem is framed or how a question is understood is a central aspect of online reading comprehension. Recent work by Taboada and Guthrie (2006) within traditional texts suggests that reading initiated by a question differs in important ways from reading that does not.

Reading to Locate Information

A second component of successful Internet reading is the ability to read and locate information that meets one's needs (International ICT Literacy Panel, 2002; Guinee, Eagleton, & Hall, 2003). The reading ability required to locate information on the Internet may very well serve as a gate-keeping skill; if one cannot locate information, one will be unable to solve any problem. New online reading skills and strategies may be required, for example, to generate effective keyword search strategies (Kuiper & Volman, 2008); to read and infer which link may be most useful within a set of search engine results (Henry, 2006); and to efficiently scan for relevant information within websites (Rouet, 2006).

Reading to Critically Evaluate Information

A third component is the ability to critically evaluate information encountered on the Internet. Critically evaluating online information includes the ability to read and evaluate the level of accuracy, reliability, and bias of information (Burbules & Callister, 2000). This presents challenges that are quite different from traditional print and media sources. The content of online information is even more diverse and commercially biased and new sources of information about authors appear, requiring new strategies for their effective use.

Reading to Synthesize Online Information

Successful Internet use also requires the ability to read and synthesize information from multiple online sources (Jenkins, 2006). Synthesis requires the reader to bring together an awareness of the reading processes and an underlying understanding of the text. The Internet introduces additional challenges to coordinate and synthesize vast amounts of information presented in multiple media formats, from a nearly unlimited and disparate set of sources (Jenkins, 2006; Rouet, 2006).

Reading and Writing to Communicate Online Information

A fifth component of successful Internet use is the ability to communicate via the Internet to seek information or share what you have learned. Emerging research suggests that the interactive processes of reading and writing have become so intertwined on the Internet that they often happen simultaneously during communication (Coiro & Dobler, 2007). Moreover, each specific communication tool on the Internet is constituted differently and presents a range of new skills, strategies, and social practices to use them effectively (Coiro et al., 2008). New types of strategic knowledge are required, for example, to effectively participate and communicate in social networking environments such as e-mail, blogs, wikis, and instant messaging (Leu et al., 2005; Lewis & Fabos, 2005).

What Do We Know About the New Literacies of Online Reading Comprehension?

Work is just emerging on the new literacies of online reading comprehension. As a result, we are merely discovering the outlines of what happens when we read online. What do we know? First, online reading comprehension appears not to be isomorphic with offline reading comprehension; additional reading comprehension skills seem to be required (Leu et al., 2005; Coiro & Dobler, 2007). One study, among sixth grade students proficient at using the Internet (Coiro & Dobler, 2007), found that online reading comprehension shared a number of similarities with offline reading comprehension, but online reading comprehension was also more complex and included notable differences. A second study found no statistically significant correlation between scores on a state reading comprehension assessment and an assessment of online reading comprehension with good psychometric properties (Leu et al., 2005). These data also suggest that additional skills are required for online and offline reading comprehension. A third study (Coiro, 2007) found that offline reading comprehension and prior knowledge contributed a statistically significant amount of variance to the prediction of online reading comprehension, but an additional 16% of independent variance was contributed by knowing students' online reading comprehension ability. Finally, case studies and videos of online reading show that students who perform low on state reading assessments, sometimes perform at unexpectedly high levels on tasks of online reading comprehension (Leu, Zawilinski, et al., 2007). Together, these results support the claim that additional skills and strategies may be required during online reading.

It is surprising to find that some struggling readers read well online (Castek, Zawilinski, McVerry, O'Byrne, & Leu, 2011). This suggests that the Internet may be a potentially supportive context for some struggling readers. Why might this be the case? Units of text are typically shorter online as readers follow informational links from one location to another seeking help in order to solve their informational problem. Shorter units of text are easier for struggling readers to process. In addition, online readers construct their own texts to read, as they choose different paths to follow. This increases engagement and makes it more likely that readers encounter text appropriate for their abilities. Also, online

texts contain multimedia, a traditionally supportive context for struggling readers. Finally, each Web page is really a graphic image and struggling readers are often quite skilled readers of information presented graphically.

There is also a third finding—that although adolescent “digital natives” may be skilled with social networking, texting, video downloads, MP3 downloads, or mash ups, they are not always as skilled with online reading comprehension, including locating and critically evaluating information (Bennett, Maton, & Kervin, 2008). We may overgeneralize adolescents’ ability to read online information effectively, from their ability to engage successfully with online social networking, texting, and video games.

What Do We Need to Know About the New Literacies of Online Reading Comprehension?

The answer to this question is simple: There is much we do not know so the need is great. We do not fully understand, for example, the reason that online and offline reading comprehension are not isomorphic. Several explanations are possible. Current results, showing a lack of correlation between the two may be due to the fact that online reading is a problem-based task while offline reading includes a wider range of comprehension tasks (see Taboada & Guthrie, 2006). Or, it may be that the reading skills required to locate information online are such bottleneck skills that students who lack this ability perform poorly online, even though they may be high performing offline readers. Or, greater levels of critical evaluation, typically required online, may be the source of the difference.

It is also likely that we can increase or decrease statistical relationships between online and offline reading comprehension by simply varying the nature of the online reading comprehension task. Online assessments that require richer, more complex use of online tools (search engines, e-mail attachments, blogs, wikis), or more complex information spaces, may generate less of a relationship with offline reading comprehension compared to online assessments that simply require the reader to read information at a single Web site. So, it is still too early to claim that the lack of isomorphism between online and offline reading is either strong or weak. That it can be demonstrated appears to be the case, but we require much more work to be able to fully understand the conditions under which the two contexts for reading require different skills and strategies.

We also do not know very much about the relative contribution of various elements of online reading comprehension to successful online reading outcomes. It is likely that skill areas often required earlier in the process (locating and evaluating information) may be more determinative of successful performance than other areas, but we have not yet evaluated this claim.

In addition, we need research on the phenomenon reported above, that some struggling readers find the Internet to be a very supportive context for reading. Prevailing wisdom in schools is that these students are not “ready” for reading on the Internet. That may be precisely opposite of what should be done for these students.

Also, we need to develop new instructional models. It is likely that these models may require one-to-one computing contexts to facilitate rapid exchange of online reading comprehension skills and strategies among students, something that initial research (Leu et al., 2005) has discovered.

Finally, we require better assessments of online reading comprehension, ones that are not only reliable and valid but also practical, easy to administer and score, and provide immediately useful information to teachers. The ones we currently have appear to be valid and reliable but they were designed for research and, as a result, require extensive time to reliably score. Currently work is taking place that seeks this broader objective (Leu, Kulikowich, Sedransk, & Coiro, 2009).

The Internet Is a Literacy Issue, Not a Technology Issue

As we consider new definitions of literacy in a deictic world, it is essential to recognize that the Internet is a literacy issue not a technology issue. Most educational systems fail to recognize this point. As a result, they create unnecessary challenges and make it more difficult to prepare a new generation skilled in the use of online information. There are two ways in which this happens.

First, public policies and assessments in literacy currently help the rich get richer and the poor get poorer in developing the ability to read and use online information effectively. How does this happen? The poorest students in any nation have the least access to the Internet at home (see Cooper, 2004). Unfortunately, it is often the case that the poorest schools are also under the greatest pressure to raise scores on tests that have nothing to do with online reading comprehension (see Henry, 2007). No state assessment of reading in the USA, for example, contains any item that measures the ability to read search engine results or evaluate the source of information appearing online for bias. In poorer schools, there is often little incentive to teach the new literacies of online reading comprehension because they simply are not tested. Thus students in the poorest schools become doubly disadvantaged: They have less access to the Internet at home, and schools do not always prepare them for the new literacies of online reading comprehension at school.

Now, consider students in the most privileged schools. Many children from advantaged communities have broadband Internet connections at home. As a result, teachers feel greater freedom to integrate the Internet into their curricula (Henry, 2007). Thus students in richer districts become doubly privileged: They have greater access to the Internet at home and they use it more often at school.

It is a cruel irony that students who most need to be prepared at school for an online age of information are precisely those who are being prepared the least. The problem stems from the fact that policy makers and educators do not yet see the Internet as a literacy issue; they see it as a technology issue.

Consider, also, a second problem, the lack of Internet integration with content curriculum. Typically, schools frame the Internet as a technology issue. This often leads to the following types of outcomes:

1. technology standards become separated from subject area standards,
2. instruction in Internet use is not taught in content classes but in a separate technology or media class,
3. someone other than the classroom teacher teaches online information use, and
4. online information and communication skills are assessed separately from subject area skills.

Greater segregation of the Internet from the content curriculum typically results; online information use is taught down the hall by someone other than the classroom teacher, often in a computer lab.

Now, consider the likely outcomes when the Internet is framed as a literacy issue:

1. technology standards become integrated within subject area standards,
2. instruction in Internet use is integrated into each subject area,
3. every classroom teacher is responsible for teaching online information and communication use, and
4. online information and communication skills are included in subject area assessments.

Clearly Internet integration with content instruction will happen faster when the Internet is defined as a literacy issue.

Literacy Is the Internet—the Internet Is Literacy

This entry began by pointing out the importance of defining literacy correctly, suggesting that literacy had become a deictic construct, largely because it increasingly takes place on the Internet. We outlined a collaborative approach to defining literacy as a deictic construct; a dual-level theory of New Literacies.

It concludes by noting that not only is literacy the Internet, but that the Internet is literacy. These two aspects of our lives are, and will be, inseparable. Recognizing the tight link between literacy and the Internet is important if we hope to understand the nature of the literacies of today while we prepare students for the literacies of tomorrow.

News Discourse

ALLAN BELL AND PHILIPPA SMITH

Applied linguists have long been intrigued by the language and discourse of news media. They recognize that media are significant producers of discourse, that media use language in linguistically interesting ways, and that media institutions and their discourses play an important role in shaping culture, politics, and social life. This entry discusses the main issues and frameworks that have arisen in the analysis of news discourse. It then exemplifies such work by way of a case-study analysis of an online newspaper story, and compares that with a hard copy version.

The Significance of News Discourse

We are surrounded by media, their products, discourses, and modalities. News is central to much media. It is the staple content of the newspaper, whether that be in traditional hard copy or the increasingly utilized online version. News bulks large as a flagship genre in radio and television broadcasting. On the Internet some of the most visited sites are news sites. Reading, hearing, or viewing news is an important social activity, which reconfigures but does not seem to diminish as news technologies change. Looking for news is by far the most prevalent information-seeking activity on the Internet in Western countries: In New Zealand, a third of the population look for news on the Internet daily (Smith et al., 2010).

News is a process that takes raw materials, reworks them, and transforms them into “a recognizable product which we accept as familiar” (Hartley, 1982, p. 7). Not only do news texts “draw upon and recirculate discourses,” they may magnify and privilege some discourses. News discourse is shaped by technology, deadlines and time restraints, restrictions on page space or air time, journalistic practices, gatekeeping by editors and copy editors, media ownership, and a myriad of other influences to which most consumers are oblivious. Without overlooking the role of other modalities such as visuals, language is central to news. The codes, conventions, and structures of news discourse in large part define the nature of news.

Discourse analysis requires close examination of the news text, both the linguistic form and other modalities such as its visual aspect. It focuses on the form of the text and how it is used in a social context—its construction, distribution, and reception. It aims to understand what are the meanings and social significance of the text (Smith & Bell, 2008).

History, Technology, and Discourse

The spread of the long-distance telegraph from the middle of the 19th century was the first crucial step in the development of modern news practices and forms. It sped up the delivery of news and required brevity. The use of the telegraph, together with related developments such as the creation of international news agencies, helped establish modern patterns of news and its discourses. The quest to get the story first before one’s competitors, and the advent of a nonchronological order for writing stories, became central to the production of news and to the craft of the journalist.

These changes involved shifts in modes of news presentation and discourse. Until the late 19th century, news was buried in the middle of the newspaper while the front page carried classified advertisements. There were often multiple headlines which told much of the story (Smith & Bell, 2008). Across the last hundred years there has been a continuing move to greater linguistic compression, most noticeably in headlines, where short, sharp lexical items are chosen and function words are dropped.

The 20th century saw radio, and then television, adopt and adapt news forms inherited from the press. The latest technological change to affect the shape of news discourse is the advent of the Internet. What began as a transfer of hard copy newspaper content and form on to the Internet is now increasingly utilizing the affordances which the new technology enables (Knox, 2009). Clickable headlines, pictures, and key words allow readers to access more detail and background. Video footage can be viewed, not just still photographs. Space restrictions on stories change—even tighter on home pages, but longer in the full stories. And there is a convergence of media forms: online newspaper sites carry video and audio as well as pictures and quotes, while television sites carry print and still photographs as well as video footage.

Frameworks for Analysis

Several frameworks for analyzing news discourse have been developed, of which the most established are those of van Dijk, Bell, and Fairclough. Van Dijk's pioneering work on newspaper stories (1988) found there were few significant differences in news discourse structure across different languages. He proposed an analytical framework bringing together production and interpretation of discourse as well as its textual analysis. Thematic analysis goes beyond microanalysis of language and concentrates on the arrangement of themes in news reports, such as narrative patterns which create dramatic tension in a story, or the nonchronological description of events, influenced by news value or relevance. Van Dijk parallels this broad semantic structure with a syntactic structure termed "schemata": the conventions and rules that organize content and the complexity of news themes.

Bell (1991) stresses the centrality of the notion of the story to news discourse, and the fact that journalists are language and discourse professionals whose job focuses on the production of text. He offers a step-by-step guide to analysis (1998), which is used to determine the event structure in a news story and establish what a story actually says happened. Analysis of events, actors, times, and places in a story "shows up inconsistencies, incoherence, gaps and ambiguities within the story, conflicting forces during the story's production by journalist and copy editor, and implications for readers' comprehension" (Garrett & Bell, 1998, p. 9). Bell stresses the importance of news values such as negativity and recency which underlie many journalistic and editorial decisions. Below we illustrate this kind of approach on a single example.

Fairclough's (1995) framework for critical discourse analysis of communicative events involves the three overlapping dimensions of text, discourse practice, and sociocultural practice. Analyzing text involves areas such as structure, vocabulary, or representation of actors through image, language, or sound. Discourse practice covers processes of text consumption, and especially production, which Fairclough divides into two threads—institutional routines such as systems of news selection, and discourse practices where texts pass through a series of transformations, for example at the hands of a copy editor. Sociocultural practice requires consideration of outside influences that affect the construction and production of a text, for example politics, the economy, or societal attitudes. Fairclough has emphasized trends towards change in contemporary media discourses, including a shift toward greater informality.

A Case Study

The best way to approach the discourse analysis of news is through a hands-on example, here by examining one article. Presenting a full close analysis of the macro and micro levels of language and discourse in this story, together with its sociocultural embedding, is impossible in the space available. We therefore concentrate on five specific areas which reveal some characteristics of news discourse: the visual design, headline and lead sentence, discourse structure, the story's sources, and unclarities in the story.

Choosing a story from a newspaper's website enables us to look at the discourse nature of the ever-increasingly important genre of online news (Boczkowski, 2004), briefly compare it with traditional hard copy treatment, and comment on both production and reader practices. A screenshot of the story is shown as Figure 1, reproduced from the website (March 4, 2010) of the *New Zealand Herald*, the country's largest circulation daily. It concerns the damage and death caused by large waves which hit a cruise ship in the Mediterranean in March 2010.

Visual Design

Our story had been placed as the third lead on the online *Herald's* home page. News home pages are routinely crammed with brief stories and advertisements competing for readers' attention. The full lead sentence in the story (that is, Paragraph 1 in Figure 1) is reproduced below, and the "newsbite" on the home page carried the same headline, picture, and opening text as in Figure 1. However, on the home page the lead sentence ends abruptly where the space runs out at the end of the fourth line of text:

A freak 8-metre-high wave has
smashed into a cruise ship
carrying nearly 2,000 people in
the Mediterranean early . . . [More](#) /

The truncation of the home page sentence in midsyntactic structure leaves what appears there blatantly incomplete, but reflects the assumption that interested readers will perform the one-movement click that takes them direct to the full story. This is much easier than the effort required to go from a hard copy newspaper's front page to locate a continuing story inside.

The appearance of the full story in Figure 1 is similar to that of a hard copy story, with three exceptions:

- All the text is left ranged (a magazine style) rather than fully justified, as it would be in standard hard copy press.
- Several lines of white space appear under the photograph caption. Compared to the hard copy press, online space is unrestricted, overturning the centuries-long squeeze on publishable story length.
- The next column to the right alongside the photo contains several hyperlinks, most notably a link to the cruise company's website. This site carries the same picture of the ship, and a detailed listing of its luxurious amenities. The ability to provide detailed further background at a click contrasts strongly with hard copy news. There more detail has to be written up by journalists and printed somewhere—compare the last paragraph of this story, which details the ship's size and amenities. The Internet enables the news organization to offer access to information which the reader is free to follow or not. Not only does this give more information, but it is information which the news organization does not have to create or rework or take responsibility for.

Figure 1 Screenshot of online news story from the *New Zealand Herald* online, March 4, 2010 (reproduced by kind permission of APN Holdings NZ Limited; copyright restrictions prevent the text being reproduced).

Later accounts on television will show actual footage, filmed by a passenger, of the wave smashing through windows into a restaurant on the ship. But it is too soon for video to be available, so this online story offers little more by way of multimodal coverage than would hard copy, except for the hyperlinks. We see here readers cast as active participants in constructing the story, with the online affordance of more background. They can email the story to friends, or put a comment on Facebook or Twitter. This implies a news discourse which is moving away from the traditional one-way communication of the hard copy newspaper, to something which can be augmented and manipulated in a variety of ways by its readers. Note nevertheless that the traditional text still remains at the core of the story.

How does the hard copy story compare with this online version, and what can this tell us about these two different modalities of press news? The story was published in print on March 5, nearly 24 hours after the online version. It had been demoted to a three-sentence item in a column of news briefs tucked away on page A15 of the hard-copy *New Zealand Herald*:

Two die as wave hits ship

An 8-m wave has smashed into a cruise ship carrying nearly 2000 people in the Mediterranean yesterday, smashing glass windshields and killing two passengers, according to officials and news reports. Another six people suffered light injuries, the Greek coast guard said. The victims were identified as a German and an Italian man.

The reason for the demotion is the time elapsed and the thorough coverage in the interim by television, which has shown the live footage. The online story itself updated the still photograph of the ship with clickable video footage at 8.16 a.m. that morning. The hard copy newspaper, then, has been left well behind in the timing of its coverage compared to both online and broadcast news.

Headline and Lead

The headline and lead sentence form the abstract of a news story. The headline in the online story “Freak wave kills two on cruise ship” is typically styled for “spot” news of accidents and disasters. It uses the lexicon of negativity—that most gripping of news values (Bell, 1991)—focused in the words “freak” and “kills.” These items stand incongruously next to “cruise ship,” with its connotations of secure luxury—reinforced by the picture and the detail given about the ship in para. 10: 10 decks with 732 “staterooms,” together with bars, pools, restaurants, and shops. This sets up a counterpoint with the disaster and death which has intruded into the passengers’ leisure.

Lead sentences are the pearls of the journalist’s craft. Deciding what to lead with is the journalist’s main task in evaluating a story, and shaping that lead takes up much of the journalist’s time. Once the lead is settled, the rest of the story falls into place below it. Leads therefore merit particular focus from analysts. There is a myth that news writing is syntactically simple, especially lead sentences. However, both van Dijk (1988) and Bell (1991) have shown this is not the case. At 36 words, this sentence (Para. 1) would be long in any genre, and its syntax is very complex. The text of the lead paragraph of the online story is as follows, showing the lines as displayed in Figure 1:

A freak 8-metre-high wave has
smashed into a cruise ship carrying
nearly 2,000 people in the
Mediterranean early today (NZ time),
smashing glass windshields and
killing two passengers, according
to officials and news reports.

The sentence contains a reduced relative clause modifying the noun that is object of the sentence: “a cruise ship [which was] carrying. . .” This is followed by an absolute clause “smashing glass windshields,” which is itself coordinated to a second such clause “and killing two passengers.” The whole is topped off by an unusual dual source attribution, “according to officials and news reports.”

The reason leads may be complex is that the journalist (or the copy editor who does a rewrite) is trying to tell as much of the story as possible in just one sentence. This particular lead sentence contains the “5 Ws and one H” of journalistic practice—who, what, where, when, why, and how—except for the “why”: the story nowhere addresses the cause of the giant waves.

The print story reproduced earlier offers a headline that is both shorter and softer than the online story: “Two die as wave hits ship.” The high-value “freak” and “kills” are gone, perhaps because the story is no longer new high-impact news.

Discourse Structure

Unlike other kinds of stories, the traditional news story is not told in chronological order (Bell, 1995). It begins with the central news event—in this case, the wave and the damage it caused—and then moves backwards and forwards in time. This is known as the “inverted pyramid” structure, by which prior and subsequent events and commentary are presented after the central news event.

Follow-up, commentary, and background are the three major structural categories which occur after the main event itself. Prior events usually bulk large, but in the present example they scarcely figure, except for the description (in the second half of para. 3) of the ship’s route at the time of the wave, from Barcelona (in Spain) to Genoa (Italy). In this story, the later paragraphs contain:

- attempts to fill out the detail of what happened: who the victims were (one German and one Italian, para. 2), location of the incident (paras. 3–4), and detail on the waves (three up to 8 meters high, para. 9);
- commentary from the French maritime authority on weather and sea conditions at the time (winds over 100 km per hour, paras. 5–6);
- consequences of the accident for the ship’s routing (returning to Barcelona), and expectations of what will happen next (paras. 4, 7, 8);
- background information about the ship (para. 10).

All these are standard categories in the discourse structure of news (Bell, 1998). The notable absence here is background on the antecedents of the central incident, that is, the causes of the extreme waves, except for a general mention of windy conditions (para. 6). The absence of explanation is typical of the immediate reporting of spot news such as an accident. Investigation of causes takes more time—and will often not get into publication.

The print story is limited to the first three sentences of the online version, which are slightly edited. The print story is shorter, not directly because of lack of space, but rather because the story has lost the news values of recency and priority (getting the story first) and so no longer merits a longer item.

Significantly, the tense of the print lead sentence shifts from the present perfect of the online story—"has smashed into"—to simple past, "smashed." The apparently minor tense difference is emblematic of a major difference in orientation. Traditional press stories are always told in the past tense, and this contrasts with broadcast news' use of present perfect, which gives the account more immediacy. We see online news deliberately adopting in its lead sentence the broadcast convention, which accords with its status as a more immediate medium. All the later sentences of the online story revert to simple past.

Sources and Intertextuality

Sources are a necessity of news practice: Journalists need sources in order to gain publishable information. Different sources routinely produce different discourses (Smith & Bell, 2007), and such intertextuality is evident here. This story has eight sources, a high number for such a short piece. They include:

- a news agency (identified underneath para. 10);
- maritime sources in Greece (paras. 2, 3), France (5, 6), and Barcelona (7, 8);
- cruise line spokesman (4, 9) and website (10);
- a French newspaper (4).

The text of the story as a whole is attributed to a news agency: the overall attribution of a story is an important component of its macrostructure. The high number of sources here reflects the media's difficulty in accessing accurate basic facts about these events.

Unclearities

Presenting a clear, unambiguous account of events is a primary goal of journalists and their organizations, yet research on news discourse shows that stories often contain significant gaps, inconsistencies, and even contradictions (Bell, 1998). Here confusion surrounds the basic "facts" of this incident, reflecting the recency of the story. Unusually, the story itself presents explicitly unresolved contradictory accounts of where the incident occurred. Locations some 300 km apart are sourced to different authorities:

Para. 3 It was unclear exactly where the incident took place. The Greek coast guard said the accident occurred near the French Mediterranean port of Marseille...

Para. 4 But the French newspaper *Le Figaro* said the accident happened off Capo de Begur, off the coast of Spain about 110 km northeast of Barcelona...

The Greek coastguard (para. 3) seems an odd source in this context, since Greece is over 2000 km away in the eastern Mediterranean. In the print story, the cuts mean that all the uncertainty over place and the range of sources is eliminated, along with the background. A second contradiction, unacknowledged within the online story, is that while the lead and headline speak of a single wave, in para. 9 the cruise company spokesman says there were three waves up to 8 meters high.

Conclusion

As this case study shows, news is a complex communicative event (Eilders, 2008). It merits ever closer scrutiny by researchers, giving attention to the pace at which news can be gathered and the locations to which it is sent. The impact of new media is increasing, with television, radio, and press available across national boundaries and the Internet offering podcasts, blogs, tweets, and other genres ancillary to online news.

The social and political practices surrounding the production and consumption of news discourse are changing. Audiences increasingly show the ability to navigate “immersive and interactive multimedia news reports” (Pavlik, 2000, p. 232), and to themselves become reporters of the news. Coverage of events often involves eye-witness accounts from “on-the-spot” civilians, as was the case with the Indian Ocean tsunami in 2004—and the participant video of the wave hitting the cruise ship in our case study.

New modes of news discourse analysis are constantly developing to address these complexities. The challenge for researchers is to provide the evidence which supports their interpretation of a text. In the words of Stuart Hall, it is necessary to “try to justify one’s reading in detail in relation to the actual practices and forms of signification used, and what meanings they seem to you to be producing” (1997, p. 9). Linguistic analytical skills applied to news discourse can serve to unpack the layers of meaning and signification which interweave both offline and online worlds.

Nolan, Francis

JONAS LINDH

Francis Nolan (1952–) is professor of phonetics in the Department of Linguistics at the University of Cambridge. According to his Web page and from a personal interview he takes “a broad, ‘expansionist’ view of phonetics, considering its scope to include all the things we can tell when a person speaks” (Nolan, 2011).

In 1980 Professor Nolan presented his thesis on speaker characteristics, which to a large extent became the basis for his book that came out in 1983 (Nolan, 1983). Through his interest in speaker characteristics it was natural that he became involved in the application of phonetics in forensics. Many, including perhaps Nolan himself, have thought of him as a skeptic, especially in the early 1980s when potential miscarriages of justice were committed due to the lack of knowledge concerning the interpretation of spectrograms, but also due to overstated conclusions (Nolan, 1990). His research covers many areas within phonetics, including intonation (Nolan & Grabe, 1997; Nolan, 2003) and connected speech processes (Nolan, 1992; Kühnert & Nolan, 1999), but this brief entry focuses on his contribution to the forensic application of phonetics.

In 1988, a solicitor contacted Professor Nolan concerning a fraud case where there were extensive speech samples recorded over the telephone from the suspect and the perpetrator. Two other analysts had reached the conclusion that there was a match while Professor Nolan intuitively doubted it. After applying acoustic formant analysis (which the other analysts had not used) a different conclusion was reached. This led him naturally to take a rather critical stance on speaker identification. The invitation from Peter French to attend the first forensic phonetic conference in York opened the way to a closer engagement with forensic phonetic practitioners. Peter French was by this time very involved in casework and interested in bringing the subject to the surface and inviting all academics with an interest in the area and with desirable knowledge that could contribute to an expansion of the subject. These conferences later led to the creation of the IAFP (International Association of Forensic Phonetics, later becoming IAFPA by adding Acoustics to the end). Professor Nolan continued publishing widely on the subject, first on methodological questions in expert speaker identification (Nolan, 1993, 1997), but also on how to prepare voice line-ups (Nolan & Grabe, 1996) and emphasizing the limitations of forensic speaker identification (Nolan, 2001). He has made a substantial contribution by bringing linguistic and phonetic models, dialectology and acoustics together to develop the area of forensic phonetics. In recent years it has become obvious that there is a crucial lack of data on phonetic and acoustic features. A Cambridge project (with Professor Nolan as principal investigator) called DyViS (Dynamic Variability in Speech, October 2005–December 2009, funded by ESRC grant RES-000-23-1248) has mitigated the problem and the speech of a very homogeneous group of young males have been recorded in a controlled environment both direct and (in the case of one speaking style) over a landline simultaneously (Nolan, McDougall, de Jong, & Hudson, 2009). Collecting and distributing such valuable data make research and descriptive statistics on features possible in a new way. Simultaneous recordings on two different channels make new experiments possible (e.g., Lawrence, Nolan, & McDougall, 2008), building on earlier research into telephone effects (Künzel, 2001, 2002; Nolan, 2002).

Professor Nolan has also contributed to the acceptance of how to express the outcome in a logical coherent framework for expert witness conclusions (French & Harrison, 2007).

The Encyclopedia of Applied Linguistics, Edited by Carol A. Chapelle.

© 2013 Blackwell Publishing Ltd. Published 2013 by Blackwell Publishing Ltd.

DOI: 10.1002/9781405198431.wbeal0870

He recognizes that population statistics and the merging of automatic techniques and auditory-acoustic methods are the most important areas in the near future, but in the meantime Professor Nolan has contributed greatly to data, knowledge, and the merging of many experimental techniques in formant measurements.

Non-Native-Speaker English Teachers

GEORGE BRAINE

Teachers of English to Speakers of Other Languages, Inc. (TESOL) is the largest international organization in the world for teachers of English as an additional language. At the time of writing, TESOL has about 12,000 members from over 140 countries. TESOL is affiliated with about 100 independent teachers' organizations in the United States and similar organizations in other countries. As a result of these affiliations, the influence of TESOL extends to over 40,000 members worldwide (see www.tesol.org).

TESOL Quarterly, the research-oriented journal published by TESOL, is probably the best-known academic journal in applied linguistics. From its inception in 1967 to the appointment of the first non-native-speaker (NNS) editor in 2005, the editor of *TESOL Quarterly* had been a native speaker (NS) of English. Another dramatic change occurred in the leadership of TESOL the following year. Since its incorporation in 1966, the president of TESOL, too, had been an NS of English. But, in 2006, the first non-native English speaker president was elected by the organization's general membership.

These two unprecedented events indicate the recognition that NNS English teachers have received from the mainstream and the empowerment that the NNS English teachers have themselves achieved in recent years. Such recognition and empowerment could be attributed to the NNS movement that has arisen since 2000. This movement, which saw its origins in the United States, has since drawn the attention of English teachers and scholars worldwide. No discussion of World Englishes or the spread of English internationally is now complete without reference to the NNS movement.

Background

Historical evidence suggests that English was being taught as a second or foreign language as far back as the 15th century. Gabriel Meurier, a Frenchman who lived in Antwerp, may have been the first NNS teacher of English we know by name. *A Treatise for to Learn to Speak French and English*, authored by Meurier, was published in 1553 (Howatt, 1984). Nowadays, the British Council (www.britishcouncil.org) estimates that English is spoken as the second language by about 375 million speakers and as a foreign language by about 750 million speakers. There is little doubt that the majority of English teachers are NNSs because these vast numbers of second and foreign language speakers would be taught mainly by indigenous NNS English teachers. For instance, China recently made English a compulsory subject from Grade 3 onward. According to recent statistics, about 230 million students were enrolled in primary, secondary, and tertiary level in China (http://www.edu.cn/jiao_yu_fa_zhan_498/20080901/t20080901_321919.shtml). Undoubtedly, the majority of these students are taught English by indigenous Chinese teachers.

Despite the strong presence of NNS English teachers worldwide, issues relating to them were not openly discussed or studied until a decade ago. This may have been because the topic is unusually sensitive and is often considered politically incorrect. The commonly accepted view in language pedagogy has been that NNS English teachers are second in knowledge and performance to NS English teachers (Phillipson, 1992, has discussed the

origins of this issue). While the authority of the NS was accepted as the norm in English-speaking countries, there appeared to be power struggles between the expatriate NS English teachers and the indigenous NNS English teachers in EFL contexts (see, e.g., Canagarajah, 1999).

The roots of the US-based NNS English teacher movement probably lie with the concept of World Englishes, first proposed by Braj Kachru and Larry Smith in the 1970s and since accepted widely by linguists. Kachru's classification of the spread of English into three concentric circles was groundbreaking because, for the first time, it showed that the NNSs in the Outer and Expanding Circles far outnumbered the NSs of English in the Inner Circle. Kachru (1992) later argued that the dichotomy between NSs and NNSs of English is functionally un insightful and linguistically questionable, especially in the context of the functions of English in multilingual societies.

If NNS English teachers needed consciousness-raising, it came with the publication of Robert Phillipson's *Linguistic Imperialism* in 1992. One topic that Phillipson dealt with was what he termed the "native speaker fallacy"—the belief that "the ideal teacher of English is a native speaker," resulting in the widely held assumption that NS English teachers are better than NNS. Phillipson (1992) challenged the fallacy by stating that NS abilities could be instilled in NNSs through teacher training, that NNSs of a language have undergone the process of learning a (second) language and are therefore better qualified to teach the language, and that language teaching is no longer synonymous with the teaching of culture and could therefore be taught by teachers who did not share the culture of NSs of the language they taught.

One of the first to explore NNS English teacher issues was Peter Medgyes, himself an NNS from Hungary, who advanced three hypotheses based on his assumption that NS and NNS English teachers are "two different species" (1994): NS and NNS English teachers differ in terms of language proficiency and teaching practice (behavior), most of the differences in teaching practice could be attributed to the discrepancy in language proficiency, and both NS and NNS English teachers could be equally good teachers on their own terms. However, Medgyes's publications were based in Britain and were largely unknown in the United States, where the NNS movement had its origins.

Birth of the Non-Native Speaker Movement

The beginning of the NNS movement was the colloquium titled "In Their Own Voices: Non-Native Speaker Professionals in TESOL" conducted at the 30th Annual TESOL Convention, held in Chicago in 1996. Well-known NNS scholars in applied linguistics as well as novices to the profession—Ulla Connor, George Braine, Suresh Canagarajah, Kamal Sridhar, Jacinta Thomas, and Devi Chitrapu—addressed issues that were of concern to them. Their highly charged, mainly personal narratives generated much enthusiasm among the audience, and the idea for a TESOL Caucus for NNSs was first proposed at the discussion that followed.

In an invited article in *TESOL Matters*, Braine (1998) pointed out that for many NNS English teachers, qualifications, ability, and experience were of little help in a job market where the invisible rule appeared to be "No NNS need apply" and where many English language teaching (ELT) administrators simply did not hire NNS teachers. The main reason appeared to be the subtle opposition to the increasing presence of foreigners in Western academia as teachers, researchers, and scholars. Braine also pointed out that this was especially ironic in ELT, considering the profession's strident championing of multiculturalism, diversity, and other sociopolitical causes on behalf of English as a second language

(ESL) students and immigrants. He further noted that NNS English teachers who return to their countries after obtaining higher degrees and teacher qualifications in the West are not always able to find work. Some language program administrators appeared to prefer unqualified NSs of English to qualified local teachers. Such local teachers were in the bewildering and frustrating position of being denied what they had been trained to do.

In 1998, the Non-Native English Speakers in TESOL (NNEST) Caucus was established, and the first formal meeting of the Caucus was held at the TESOL Convention in 1999, which coincided with the publication of Braine's *Non-Native Educators in English Language Teaching* (1999). The overall aim of the Caucus was to strengthen effective teaching and learning of English around the world while respecting individuals' language rights. Specifically, the major goals were to

- create a nondiscriminatory professional environment for all TESOL members regardless of native language and place of birth,
- encourage the formal and informal gatherings of NNSs at TESOL and affiliate conferences,
- encourage research and publications on the role of NNS teachers in ESL and EFL contexts, and
- promote the role of NNS members in TESOL and affiliate leadership positions. (See <http://nnest.asu.edu>.)

The Caucus used a biannual newsletter, an active listserv, and a Web site to publicize its activities and disseminate information among the membership. The Web site also listed a bibliography of publications that have appeared on the topic. The Caucus was fortunate in the leaders it elected and the enthusiasm and dedication of its members. It appeared to have released a flood of pent-up energy in the empowerment of NNS English teachers. Through outreach activities, well-attended meetings, an actively subscribed listserv, conference presentations, and publications, the Caucus created a vibrant TESOL community that had attracted 1,700 members by 2008.

In 2008, by consensus of its members, the Caucus transformed itself into an Interest Section of the TESOL organizations. Caucuses are mainly for advocacy whereas Interest Sections are more concerned with professional issues. This transition marked another milestone of the movement with its emergence as a full-fledged area of research.

Reflecting on Achievements

More than ten years after the formation of the Caucus, it is time to reflect on the achievements of the NNS movement. What began as an attempt by a small group of TESOL members has now become a worldwide movement. Three of the original objectives—to encourage the formal and informal gatherings of NNSs at TESOL and affiliate conferences, to encourage research and publications on the role of NNS teachers in ESL and English as a foreign language (EFL) contexts, and to promote the role of NNS members in TESOL and affiliate leadership positions—have been achieved beyond expectations. The first objective, to create a nondiscriminatory professional environment for all TESOL members regardless of native language and place of birth, is more an ideal than a pragmatic reality, and the NNS movement will continue to work toward these ends. More specifically, the major achievements are the rise in self-esteem, a surge in academic research and publications on NNS issues, and leadership in TESOL. I will close this entry by commenting on each of these achievements.

Rise in Self-Esteem

When a suitable name for the Caucus was contemplated in 1997–8, some colleagues did not support the inclusion of the term “non-native speaker” in the name and suggested alternatives such as “second language-speaking professionals”, “second language-teaching professionals”, and “English teachers speaking other languages.” Their reticence came as no surprise. As stated earlier, NNS English teachers had long been considered second rate, which in turn may have caused a certain lack of self-confidence among them.

In sharp contrast, the period since 1998 has seen a surge in the use of the term “non-native speaker” in scholarly presentations and publications as well as in informal discussions, both face-to-face and online. Now, it is politically correct to use the term and NS scholars and teachers no longer hesitate to use it. But among NNS English teachers, particularly, the change has been dramatic. No longer afraid to call themselves NNSs, they have transformed the landscape of academic presentations and publications. For instance, since the formation of the Caucus, the annual TESOL Conventions have included about 15–20 presentations on NNS issues, with the term “non-native-speaker” in the title. Many of these presentations have been by NNSs themselves.

Surge in Academic Research and Publications on Non-Native-Speaker Issues

The NNS bibliography, available on the Interest Section Web site, lists more than 200 publications. Most of them have appeared since the formation of the Caucus, and many have been authored by NNSs.

Since the appearance of Braine (1999), three major anthologies have appeared: Kamhi-Stein (2004), Llorca (2005), and Braine (2005). Braine (2010) has recently brought out a volume that sums up the achievements of the NNS movement, and describes the challenges faced by NNS English teachers.

Language Teaching publishes state-of-the-art articles on topics and areas related to second language teaching and learning. In volume 41, the state-of-the-art article was “Non-native English-speaking English language teachers: History and research,” authored by Lucie Moussu and Enric Llorca (2008). This publication could be seen as a milestone in, and the coming of age of, the NNS movement. The article had 165 items in the list of references, a rich source of information for future researchers and scholars.

Leadership in TESOL

As mentioned earlier, an NNS, Suresh Canagarajah, became editor of *TESOL Quarterly* in 2005, and another, Jun Liu, was elected president of TESOL for 2006–7. Canagarajah was a presenter at the historic TESOL colloquium of 1996, and Liu is a founding member of the NNEST Caucus and was its second chair. The third chair of the Caucus, Lia Kamhi-Stein, has served as a board member of TESOL. Another active member of the Caucus, Brock Brady, has also been a TESOL board member and president of TESOL. In addition, more and more NNSs are taking leadership roles in applied linguistics and English language teaching.

Norms of Translation

THEO HERMANS

If we assume that translation serves a communicative purpose, some degree of coordination between the participants in the process—sender and receiver, *ego* and *alter*—will be necessary. The concept of norms has been deployed in the study of translation in an attempt to gain a better understanding of the factors governing the communicative behavior of translators and the interaction between translators and their audiences. There has been a good deal of theoretical reflection on the role of norms in the context of translation and translation studies (Toury, 1980, 1995; Frank & Schultze, 1988; Hermans, 1991, 1996, 1999; Nord, 1991; Chesterman, 1993, 1997; Schäffner, 1997) and the issue has gained renewed attention with the recent interest in the sociology of translation (Wolf & Fukari, 2007; Pym, Shlesinger, & Simeoni, 2008). In what follows I will first set out the concept of norms in general terms before explaining how it has been used in the study of translation. I will then consider some of the applications and implications of the norms concept in translation studies.

The Concept of Norms

The concept of norms has proved useful in a range of social sciences, from law and ethics to social psychology and international relations (Hjort, 1992), but there is no unanimity as regards terminology or the exact distinctions between norms, conventions, rules, constraints, and other similar terms.

The term “norm” may refer both to a regularity in behavior and to the mechanism which accounts for this regularity. The mechanism has a socially regulatory function and comprises a psychological as well as a social dimension. It mediates between the individual and the collective, between the individual’s intentions, choices, and expectations, and collectively held beliefs, values, and preferences. Norms bear on the interaction between people, more especially on the degree of coordination required for the continued, more or less harmonious coexistence with others in a group. Norms contribute to the stability of interpersonal relations by reducing uncertainty about how others will act. By generalizing from past experience and allowing projections concerning similar types of situation in the future, norms help to make behavior more predictable.

Translation in a social environment involves transactions between several parties who have an interest in these transactions taking place. The translator, as one of the decision-making parties in the transaction, is an agent whose actions are neither wholly free nor predetermined, especially as the entire process is played out in the context of existing social structures. The more the parties can coordinate their actions, the greater the likelihood that they will consider their interaction successful.

To appreciate the role of norms and conventions in solving interpersonal coordination problems, we may start from the definition of convention provided by the American philosopher David Lewis (1969). Lewis describes conventions as regularities in behavior which emerge as contingent solutions to recurrent problems of interpersonal coordination. The solutions are contingent in that they are neither necessary nor impossible: they could

2 NORMS OF TRANSLATION

have been different. If they prove effective, these solutions become the preferred course of action for individuals in a given type of situation. Conventions grow from precedent into social habit. They do not have to be explicitly agreed, but they presuppose a degree of common knowledge and acceptance. They imply reciprocal expectations and the expectation of expectations: the expectation of others that, in a given situation, I will adopt a certain course of action, and my expectation that others expect me to adopt that course of action.

Conventions are not norms, although the distinction is not always made and conventions are sometimes regarded as implicit norms or “quasi-norms” (Lewis, 1969, p. 97; Hjort, 1990, p. 43). They can, however, become norms by falling victim to their own success. If a convention has served its purpose sufficiently well for long enough, the mutually shared expectation about what course of action to adopt in certain types of situation may grow beyond a mere preference and acquire a binding character. At that point the modality of the expectation changes from cognitive to normative (Galtung, 1959). Cognitive expectations are willing to adjust to changing events; when something unexpected happens, the expectation accommodates the new information and changes accordingly. Normative expectations, by contrast, are unwilling to learn or adjust; when things happen which do not accord with the expectation, the latter is kept intact and “correct” behavior continues to be expected at the next occurrence. Niklas Luhmann speaks of norms as “counterfactually stabilised behavioral expectations” (1995, p. 321; 2008, p. 39). Whereas cognitive expectations respond to what “is,” normative expectations stipulate what “ought” to be the case.

Norms can be understood as stronger, prescriptive versions of conventions. Like conventions, norms derive their legitimacy from shared knowledge and mutual expectations; on the individual level, they are largely internalized. Unlike conventions, norms have a directive character: They tell individuals not just how others expect them to behave but how others prefer them to behave. Norms imply that there is a course of action which is more or less strongly preferred because it is accepted as proper or correct or appropriate.

The directive force of a norm is a matter of social pressure, backed up with inducements and rewards or the threat of sanctions. Hence norms may act as constraints on the individuals’ decision making by foreclosing certain options, even though these remain available in principle. At the same time norms suggest, more or less emphatically, a particular selection from among the range of possibilities, working as a problem-solving device by offering ready-made templates for action. They cover the entire range of preferences and permissions, stretching as far as prescriptions at one end and proscriptions at the other. In all these manifestations they help to increase predictability by reducing the risk of communication misfiring.

Norms may be strong or weak, more or less durable, and narrow or broad in scope. They can and will be breached, but they are able to cope with a relatively large amount of discrepant behavior. In this sense norms do not preclude conscious agency or erratic conduct. To the extent, however, that norms are inculcated as part of an individual’s socialization, they become internalized as dispositions, propensities to act in certain ways. Because they form part of the fabric of social expectations, norms provide relative stability and hence security; while they change in response to changing values and persistent or conspicuous transgressions, they do so more slowly than individual behavior. In this respect the relation between behavior and norms is similar to that between *parole* and *langue*, or event and structure.

As the prescriptive force of norms increases from the permissive to the mandatory, they move away from conventions toward rules, which may be understood as institutionalized, usually explicit obligations and prohibitions issued by an identifiable authority with the power to impose specific sanctions for transgressions.

Norms in Translation Studies

With respect to translation, norms are relevant only to the extent that translators or other participants in the transaction make decisions. In an influential essay from 1967, the Czech theorist Jiří Levý invoked game theory to describe translating as a decision-making process: Between the two extremes of total predictability (decisions necessitated, for example, by grammatical categories) and total unpredictability (wholly idiosyncratic one-off choices), each move represents a choice from among a given set of alternatives and in turn conditions the next move. Elsewhere Levý, and shortly afterwards Anton Popovič, saw two norms governing the translator's decision making: one that was reproductive and concerned with how to represent the original, and one that was productive and concerned with the well-formedness of the new text. Different historical periods, they suggested, put the emphasis now on one and then on the other norm and valued translations accordingly. The norms in each case were those factors that constrained the translator's freedom of choice (Levý, 1969; Popovič, 1976). Both Levý and Popovič drew on the Czech structuralist Jan Mukařovský, who in the 1930s and 1940s had described the individual work of art as "a complex tangle of norms" and a "confrontation of heterogeneous norms" (1978, p. 52), adding that audiences might well project different norms on a work of art than those initially observed by its creator.

Much the same approach was taken by Gideon Toury (1995), who made the norms concept a central plank in his descriptivist program for the study of translation. Toury saw norms as performance instructions for translators and distinguished different kinds of norms operating at different stages of the translation process. Preliminary norms govern the choice of what to translate in the first place; the initial norm steers the translator either toward preserving as much as possible of the original or toward producing a well-formed new text. Various operational norms guide decision making during the actual business of translating, with matricial norms regulating the macrostructure of the text and textual-linguistic norms affecting microstructures. The relevance of norms in this outlook is that the sum of the choices made by the translator determines the shape of the end product and hence not just the nature of the relation between the translation and its proto-text but also the way the translation is likely to be perceived by the audience for which it is intended.

Whereas Toury approached norms very much from the point of view of the translator's decision making, Andrew Chesterman took the interaction between translators, audiences, and fellow translators into account, and drew on theoretical discussions in other disciplines. Apart from the social and ethical norms which govern communication in general, Chesterman (1997, pp. 175–86) distinguished translation-specific "technical" norms, which he subdivided into product or expectancy norms on the one hand, and process or production norms on the other. Product or expectancy norms reflect the expectation of what a translation should look like. They largely determine what will be accepted as proper or legitimate translation by a particular community and thus stake out the perimeter of the concept of translation for that community. They correspond to what Christiane Nord (1991) had previously called the constitutive conventions of translation, which distinguish between translation and other kinds of rewriting such as parody or adaptation.

Chesterman's process or production norms are broken up into three kinds: an accountability norm, which is ethical in nature and regulates personal relations between translators and other stakeholders such as authors, commissioners, clients, readers, and fellow translators; a communication norm, which stipulates that translators should optimize communication in accordance with Gricean maxims; and finally, and most importantly, a relation norm, which ensures that "an appropriate relation of relevant similarity is established and maintained between the source text and the target text" (1997, p. 69). What constitutes

relevant similarity, what type of similarity is considered appropriate, and how it is to be achieved will depend on the circumstances; these may include the translation brief or a particular translation tradition, the supposed needs of a prospective audience, or the type of original to be translated. All the process or production norms operate at a level below that of product or expectancy norms. Christiane Nord speaks here of regulative conventions, in that they regulate the kind of translation that will result.

Only the third of Chesterman's process or production norms is properly a translation norm; the others are not exclusive to translation. In other words, translation seems to be affected by a multiplicity of norms, but many of these apply to all manner of communication and indeed all manner of behavior. Nevertheless the importance of the norms concept for translation is that it allows a revision of the traditional notion of what constitutes a correct translation. Considered from a norm-theoretical point of view, correctness in translation cannot be predetermined but is a matter of compliance with prevailing norms of translation. Toury argued that norms give substance to equivalence. In his view, if a text is accepted as a translation, it follows axiomatically that the relation of equivalence between the translation and its original obtains; norms determine the concrete shape of that equivalence relation in specific instances. Adherents of functionalist approaches to translation, such as *skopos* theorists Hans Vermeer and Christiane Nord (see Nord, 1997), have suggested that equivalence is an inappropriate term in this context and that translations can be measured in terms of their "adequacy" to the context in which they are deployed; this adequacy involves respect for or violation of norms.

Applications and Implications

The introduction of the concept of norms into translation studies enabled the contextualization of translation and offered a tool for historical research at a time when cultural rather than linguistic factors came to be seen as relevant to understanding translation in its social manifestations. Whereas early theorists like Levý and Toury treated norms primarily as constraints which simplified the translator's decision making by foreclosing undesirable options, subsequent approaches stressed the interaction between various stakeholders as well as the importance of ideological values underpinning social norms. Others shifted the emphasis from observance, stability, and the confirmation of the status quo to norm breaking and its potential to challenge the social order.

Whatever the emphasis, researchers have faced the problem of identifying translation norms. Many decisions translators make can be ascribed to norms governing the acceptability of texts as such, without necessarily involving translation-specific norms. Separating out the demands stemming from the kinds of texts for which translation caters from normative expectations specific to translation is problematic because translations are never just translations. They are translated novels or contracts or speeches or recipes, and they are likely to defer to the rules governing textual well-formedness in these genres. In this sense, but taking a broader view, Tejaswini Niranjana suggests that translation is overdetermined by religious, racial, sexual, and economic discourses (1992, p. 21). An additional difficulty is that norms are not directly observable. They must be inferred, either from statements about them or from behavior. In neither case is the inference without risk. Statements about norms may reflect individual intentions or attitudes rather than shared expectations, and behavior, even recurrent behavior or patterns of behavior, may be explained in multiple ways. From a methodological point of view it seems obvious that studying translation through the prism of norm theory requires a substantial number of translations, so that repeated recourse to certain options can gain relief against the backdrop

of available alternatives. Even then the choices made need to be further contextualized with reference to such things as commercial success or failure, critical approval or rebuke, prevailing models and explicit normative statements. Certainty as to the impact of norms on the translator's choices is not to be had, and in any case the lines separating individual preferences, conventions, norms, and rules remain blurred. Retranslations as well as translations which have caused controversy tend to be particularly rewarding objects for study, as revisions and critical debate bring the players' assumptions and expectations to the surface.

The idea that translation is overdetermined by other discourses has implications for translator training. Learning to translate means acquiring the knowledge and skill necessary to produce adequate translations, which in turn means the ability to negotiate the demands of the relevant discourses. The process amounts, in Pierre Bourdieu's terminology, to the acquisition of an appropriate *habitus* enabling the novice translator to become a player in the field. Training, however, does more than merely inculcate routines. Through examples of good practice and analysis of errors it fosters conscious awareness of the rules of the game. The competent translator should therefore be able not just to translate in accordance with relevant expectations but to decide when it is right or appropriate either to follow suit or to transgress—together with a realistic assessment of the consequences of these decisions.

Viewed in a broader cultural and historical context, translation norms in their totality can be said to inform the translation poetics of particular periods and cultures. A poetics may be understood as made up of a body of mostly normative textual expectations together with a set of canonical models and practices. A translation poetics in this broad sense largely determines what a culture, or a relevant subsection of it, selects for translation from outside its own sphere, how it will process the data, and how the resulting translations are likely to be received. The inclusions and exclusions, the modes of translation that are chosen or rejected, and the public response to the end products are indicative of how that culture sees itself. Cultures may adopt welcoming or defensive stances, they may translate out of a sense of need or curiosity, or because the choice whether or not to translate is denied them. Whatever the configuration in particular instances, a translation poetics provides an index of cultural self-perception and self-definition, since such definitions involve positioning oneself in relation to otherness.

The study of norms is not itself a normative activity. But if we study norm complexes in their historical setting, we need to find a way to translate them into our contemporary disciplinary idiom and, more often than not, across natural languages. The study of translation and translations must translate, in one way or another. If translation is a norm-governed activity, it follows that the scholarly translation of translation which takes place in translation studies cannot entirely avoid being contaminated by its object. This calls into doubt the neat separation between object-level and meta-level. It is a predicament students of translation share with ethnographers and historians, and there is no easy solution to it. Like ethnography and historiography, translation studies have devised ways of living with the paradox. They have done so primarily, in the last decade or so, by becoming increasingly self-reflexive and by drawing on the ethical norms regulating professional translating as well as those governing academic scholarship and research. The concept of norms has thus gained an unexpected relevance, not just as a tool to unlock translation but as an instrument of disciplinary reflection.

Norris, Sigrid

IRMENGARD WOHLFART

Associate Professor Sigrid Norris (b. 1961) is Director of the Multimodal Research Centre (MRC, at www.multimodalresearch.org/) at Auckland University of Technology (AUT), New Zealand. Sigrid Norris dynamically supports MRC research, supervises PhD and master's degree students, and lectures at postgraduate level in the School of Communication Studies, while also networking worldwide (e.g., Norris, 2011a). Before she joined AUT, she taught in the Department of Communication, Culture, and Technology at Georgetown University, Washington, DC and in the Department of English, Linguistics, and Speech at the University of Mary Washington, Fredericksburg, Virginia. Her work background includes language teaching and translation, librarian work, and engagements in public relations.

Sigrid Norris is one of the leading academics in the areas of mediated discourse analysis and multimodal interaction analysis. She is most widely known for the theoretical and methodological framework that she established for this interdisciplinary area of inquiry. She is a prolific writer of academic texts that explore and develop various aspects of her theory and method and their applications. These have been published in numerous books, edited volumes, and journals. She also has published poetry that deals with perceptions during fieldwork (Norris, 2008).

Born and raised in North Rhine-Westphalia in Germany, Sigrid Norris acquired her background in inorganic chemistry at the University of Bayreuth in Germany. She then studied at George Washington University in Washington, DC, where she turned her interest to the study of language and creative writing, completing a BA in Russian Language and Literature. Later, at Georgetown University, she turned toward linguistics, communication, and identity construction. In 1997 she received her MS in Linguistics under Deborah Tannen's supervision, and in 2002 achieved her PhD in Linguistics with distinction under the guidance of Ron Scollon.

Norris's research interests span a range of fields. For instance, she uses video ethnography and sociolinguistic interviews to investigate identity construction in everyday life (Norris, 2006) as well as long-term (Norris, 2010); she investigates workplace practices; the politics of national and ethnicity identity (Norris, 2007); the embodied/disembodied interface in modes; the interconnected nature of senses and communication modes of teacher, learner, and horse in riding lessons; and she instigated a project in geosemiotics and the use of signage in place across the world. But above all she focuses on the theoretical and methodological bases of multimodal interaction analysis, analysis of multiparty interactions, multimodal transcription, and the analysis of multimodal personal identity construction. Her work is strongly influenced by the late Ron Scollon's work on mediated discourse analysis; Erving Goffman's work; Gumperz and Tannen's interactional sociolinguistics; and Kress and Van Leeuwen's approach to multimodality.

In her PhD project, Norris (2002a) introduced a theoretical framework for multimodal discourse analysis, applying these theoretical notions to exploring phenomena of identity construction in an extended ethnographic study. Building on and developing mediated discourse analysis, Norris's framework pushes the boundaries of conventional linguistics through analytical inclusion of simultaneous actions and settings, which were traditionally

seen as context. Her theory, introduced in her thesis, consists of the concepts of a foreground–background continuum and modal density, and Norris demonstrated that these two notions allow insight into a social actor’s levels of attention/awareness given to simultaneous actions and into the dimensions of a social actor’s identity construction.

In her book *Analyzing Multimodal Interaction: A Methodological Framework*, Norris (2004) details the functions and wide applicability of her methodological framework for analysis for researchers and students, asserting and exemplifying the multimodality of interactions. In *Discourse in Action: Introducing Mediated Discourse Analysis*, Sigrid Norris and Rodney H. Jones (2005) brought together influential academics to present an edited volume, which the London academic Gunther Kress (2005, p. 208) describes as part of “a paradigm-shift,” as “a new domain [. . .] being staked out, the domain of human action as meaning.” No longer is language necessarily highest in the hierarchy of communicative modes, no longer necessarily the focus of attention. Rather, the question of discourse as social action is approached through first raising the question of what kind of action is taken; and only after this is dealt with, the role of discourse in this action is explored.

In *Identity in Interaction*, Norris (2010) reviews and illustrates the development from discourse analysis to multimodal interaction analysis, from the analysis of spoken language to a holistic analysis of identity construction displayed in a range of observable communicative modes during interactions. While analysis starts with the focal point of interaction, as is common in discourse analysis, Norris incorporates less focused and unfocused mediated actions as well as frozen actions entailed in material objects, reinforcing her concept of a foreground–background continuum and redefining the concept of site of engagement. Another fresh concept is that of three discourse layers, namely outer layers, which refer to the wider societal/institutional forces a social actor has to deal with and respond to; intermediary layers, which refer to the forces of the actor’s social network; and central layers of discourse, in which the social actor truly is the agent and enforces actions on others. Another of Norris’s innovative concepts is that in simultaneous interactions these layers of discourse interweave with and generate vertical layers of a social actor’s identity element construction, with outer layers of discourse creating general identity elements; intermediary layers of discourse producing continuous identity elements; and central layers of discourse producing immediate identity elements. Norris also emphasizes that any social-time-place of a social actor in interaction always involves layered discourses. This social-time-place refers to the unique and irreproducible situation of a social interaction.

Sigrid Norris’s website (www.sigridnorris.com) also allows a glance into her work and interests, and publications are referred to below.

Norton, Bonny

CHRISTINA HIGGINS

Bonny Norton is Professor and Distinguished University Scholar in the Department of Language and Literacy Education at the University of British Columbia (UBC), Canada, where she has received both the Killam Teaching Award (2003) and the Killam Research Prize (2007) for her exemplary contributions to the field of applied linguistics. In 2011, Norton became the inaugural recipient of the "Second Language Leadership Through Research" Award from the American Educational Research Association.

Norton's research addresses identity and language learning, applied linguistics and international development, and critical literacy. In addition to her scholarship, which includes her widely cited monograph, *Identity and Language Learning: Gender, Ethnicity and Educational Change* (2000), three edited books, and numerous research articles and book chapters, she has pursued her dedication to these areas as founding coeditor of the *Critical Language and Literacy Studies* book series, published by Multilingual Matters (with Alastair Pennycook and Vaidehi Ramanathan), and through her service to the field. She was teaching issues editor of the *TESOL Quarterly* from 1994 to 2007, and she is cofounder, with Sinfree Makoni and Pippa Stein, of the AILA Research Network on Applied Linguistics and Literacy in Africa and the Diaspora (www.renafrica.org).

Born and raised in South Africa, Norton has long had an interest in critical approaches to language and literacy practices in multilingual contexts, and her first publication in *TESOL Quarterly* (Norton Peirce, 1989) was a cowinner of the 1990 Malkemes Prize for "opening a new era in the profession" for integrating linguistics, politics, and pedagogy at a fundamental level. After earning degrees in education and applied linguistics at the University of Witwatersrand (Wits), and teaching at high school in Johannesburg, Norton earned her MA in theoretical linguistics at Reading University in England. She then joined the Educational Testing Service in Princeton, New Jersey, where she worked as a TOEFL test developer from 1984 to 1987. Her interest in language assessment and social change arose from this work, with an early key publication in the *Harvard Educational Review* (Norton Peirce & Stein, 1995). Another publication on "Demystifying the TOEFL Reading Test" won the 1994 International Language Testing Association Award for the best article on language testing (Norton Peirce, 1992). After completing her PhD in language education at the Ontario Institute for Studies in Education (OISE), at the University of Toronto, Norton was a visiting scholar at Wits University, a SSHRC postdoctoral fellow at OISE, and a USA Spencer postdoctoral fellow at McMaster University. She joined the faculty in the Department of Language and Literacy Education at UBC in 1996.

Norton is best known for her work on second language learning and identity, and for developing the sociological construct of *investment* to complement the psychological construct of *motivation* (Norton Peirce, 1995; Norton, 1997, 2000). After researching immigrant second language learners in Canada, Norton found that learners could not be unproblematically defined as either motivated or unmotivated. Instead, she recognized that learners construct their identities as second language speakers in response to social and historical relations with their target language communities, and with reference to their cultural past and hopes for the future. Learners invest in a target language with the understanding that they will acquire a wider range of symbolic and material resources, which will increase the

value of their social and cultural power. Access and privilege shape learners' investments since they must navigate frequently inequitable social structures as well as their own human agency. In this view, while a learner may be highly motivated, he or she might not be invested in the language practices of a given classroom or community, which may, for example, be racist, sexist, elitist, or homophobic. In Norton's research, some ESL learners were able to claim legitimacy over time by negotiating "the right to speak," but others did not experience such access, and hence, chose not to invest in the identity of the ESL learner/speaker. Such findings led Norton to more closely examine how gender plays a role in identity formation in language learning (Norton & Pavlenko, 2004), and to explore how critical pedagogies can open up new spaces for learners (Norton & Toohey, 2004). Since Norton's seminal publications, the concept of investment has been taken up by many applied linguists in contexts ranging from academic language socialization (McKay & Wong, 1996) to heritage language learning (Potowski, 2004; Wong & Xiao, 2010) and the learning of English as an international language (Gu, 2008).

Other constructs related to investment that Norton has brought to the center of debates in applied linguistics are *imagined communities* and *imagined identities*. Second language learners can claim identities as legitimate speakers if they can forge connections with particular communities of language users. These communities are often imagined communities since they may be far removed from the learners, or they may simply be out of reach due to structural constraints. As an illustration, Norton (2000) shows how two adult immigrant language learners who were highly invested in imagined communities outside their adult ESL class eventually dropped out since their imagined identities were not validated by their ESL teachers. These topics are further explored in a thematic volume that Norton coedited with Yasuko Kanno in the *Journal of Language, Identity and Education* (Kanno & Norton, 2003).

While she continues to write about identity and English-language learning around the world, Norton has turned her attention more squarely back to sub-Saharan Africa in recent years, where she has combined her long-standing interest in identity with the role of critical literacies in international development (Mutonyi & Norton, 2007; Tembe & Norton, 2008). After serving as a plenary speaker at the third Pan-African Conference on Reading in Kampala, Uganda, in 2003, Norton began working closely with both Ugandan and UBC colleagues on major grant-funded projects on literacy and development. As much of this work has explored how learners' literacy experiences relate to their social worlds, Norton has often focused on young people's health literacies in the context of HIV/AIDS education and prevention. Her research has examined how peer education offers opportunities for critical responses to the threat of HIV (Norton & Mutonyi, 2007), and how the larger discourses in HIV/AIDS research govern official responses to the pandemic (Norton & Mutonyi, 2010). Her passion for working to promote deeper understandings of the links between literacy, education, and public health are clearly reflected in her latest edited volume, *Language and HIV/AIDS*, which she co-edited with Christina Higgins (Higgins & Norton, 2010). As one reviewer wrote, "Applied linguistics doesn't get any better than this" (Fonken, 2011, p. 126).

Bonny Norton's dedication to applied linguistics as a vehicle for social change and empowerment is inspiring, and her enthusiasm is tireless. Still, despite a long list of commitments and constant travel for research and invited talks, one of Norton's best qualities is that she always finds time to give encouraging feedback to others, particularly emerging scholars who are finding their way in a complex and exciting field.

Nunan, David

KATHLEEN M. BAILEY

David Charles Nunan was born in Broken Hill, New South Wales, Australia in 1949. He describes himself as the child of working-class parents and says he might have been destined to a life in the mines, had he not been passionate about surfing and writing.

Education

Nunan's education included a bachelor of arts in English (1971) and a diploma in education (1972) from the University of New South Wales. He then completed a diploma in education with a specialty in English language teaching at the University of Exeter (1977), followed by a master's of education there (1978). He later did his PhD in educational psycholinguistics at Flinders University in Australia in 1984.

Nunan's educational experiences were interspersed with a variety of early work experiences that took him to three different continents. He served as an instructor in the Institute of Languages of the University of New South Wales from 1973 to 1976. Then, while he was working on his degree at the University of Exeter in the UK, he was a lecturer for the Bell Educational Trust in Norwich from 1976 to 1978. From 1978 to 1980 he served as a lecturer and curriculum developer in TESOL (teaching English to speakers of other languages) at Chulalongkorn University in Bangkok. From there he moved to Adelaide, where he was the ESL (English as a second language) methodologist at the College of Advanced Education. His next move was to be the Founding Director of the National Curriculum Resource Centre, a position funded by the Australian Department of Immigration and Ethnic Affairs. This work was to play a seminal role in both Australian applied linguistics and in Nunan's own professional development. In his "academic autobiography" (Nunan, 2010), Nunan wrote, "The DIEA officials did not seem to have much idea of exactly what they wanted other than the Centre was intended to give the Adult Migrant Education Program a great sense of professional coherence and direction, so I would have pretty much a free hand." This organization was later moved to MacQuarie University in Sydney, where it was called the National Center for English Language Teaching and Research (NCELTR). There, with several colleagues (notably Geoff Brindley, Anne Burns, Jill Burton, Jenny Hammond, Sue Hood, Gurd Stabler, Gillian Wigglesworth, and Ken Willing), Nunan would influence Australian teacher education, curriculum design, and language assessment. And through his publications and those of NCELTR in general, the NCELTR team would have an impact on these same topical areas around the world.

Nunan calls himself a generalist (see Nunan, 2010), but he has surprising depth in a number of key areas in language teaching pedagogy, research methodology, second language acquisition, and teacher education. This biography will briefly summarize his work in four of these topical areas: (a) in pedagogy, innovations in curriculum design and methodology; (b) in research methodology, action research; (c) in second language acquisition, strategy research; and (d) in teacher education, where his focus has been largely on professionalism and professional development.

Innovations in Curriculum Design and Methodology

Nunan has written a great deal about language syllabus design and curriculum development. The late 1980s were a particularly productive time for him in terms of these topics, with three classic books appearing in two years: *Syllabus Design* (1988a), *The Learner-centred Curriculum* (1988b)—a volume that later was published in a Chinese edition—and *Designing Tasks for the Communicative Classroom* (1989).

This last book of the three mentioned above (Nunan, 1989) represents one of Nunan's particular areas of interest: task-based learning and teaching. In fact, along with Ellis (2003) and others, Nunan helped to define and promote this movement, which was fueled in part by second language acquisition research. When his publisher asked him to produce a second edition of the original book on designing tasks, Nunan found that the field had changed so drastically, and that there had been so much work on this topic, that an entirely new book was needed. As a result, he produced another volume, *Task-based Language Teaching*, which appeared in 2004.

Influence on Action Research in Applied Linguistics and Language Teaching

One of Nunan's main intellectual contributions to language teaching and applied linguistics worldwide is his work on language classroom research in general (Nunan & Bailey, 2009) and action research in particular (see, e.g., Nunan, 1990). Action research is a method of addressing issues through a cycle of observing, planning, acting, and reflecting on the outcomes of the procedure, which is repeated as the research questions and research focus evolve (van Lier, 1994). Although the method was begun in the United States by the sociologist Kurt Lewin, it was overshadowed in US academic circles by "large N" quantitative research. Nevertheless, action research survived in the UK and then later thrived in Australia, largely through the influence of the Deakin University group (see publications by Carr, Henry, Kemmis, and McTaggart, in various combinations of coauthorship) in first language education and of Nunan and his colleagues in the NCELTR in second language education.

Through the publications and workshops offered by Nunan and his NCELTR colleagues, action research gradually began to influence language education as a viable research method throughout the world—but perhaps particularly in Australia (see, e.g., the "Teachers' Voices" series edited by Burns, de Silva Joyce, & Hood, 2000); Hong Kong (e.g., Mok, 1997); Italy (see volume 29 of *Perspectives, A Journal of TESOL Italy*); and the United States (see, e.g., Snow, Hyland, Kamhi-Stein, & Harclerode Yu, 1996).

Second Language Acquisition (SLA) Strategy Research

Nunan has also been involved in second language acquisition research—both in providing syntheses for teachers (see, e.g., Nunan, 1996a) and in conducting and editing original research. His own contributions in this area focus largely on language learning strategies (Nunan, 1996b, 2002; Nunan, Lai, & Keobke, 1999). Many of the grants he received during his academic career were focused on this topic.

Teacher Education, Professionalism, and Professional Development

Nunan's substantial influence on language teacher education derives from his publications, his university teaching posts, and the lectures and workshops he has given around the

world. With Jack Richards, he produced the first edited volume on *Second Language Teacher Education* (Richards & Nunan, 1990). This book was later produced in a Chinese edition. He edited a book on collaborative language learning and teaching and coedited a volume on change in language education (see “Suggested Readings” at the end of this entry). He coauthored a book entitled *The Self-Directed Teacher: Managing the Learning Process* (Nunan & Lamb, 1996), as well as one on professional development for language teachers (Bailey, Curtis, & Nunan, 2001), which was also later published in a Chinese edition.

A great deal of Nunan’s influence as a teacher educator is not embodied in his publications, however. Throughout his career he has been very active in teaching courses, giving workshops and plenary presentations, and running teacher education programs. As of this writing, he has given courses, seminars, workshops, and other presentations in at least 38 countries: Argentina, Australia, Brazil, Cambodia, Canada, Chile, China, Colombia, Costa Rica, the Dominican Republic, El Salvador, France, Germany, Guatemala, Indonesia, Italy, Japan, Korea, Malaysia, Mexico, Oman, Papua New Guinea, Peru, the Philippines, Singapore, Spain, Sri Lanka, Sweden, Switzerland, Taiwan, Thailand, Turkey, the UAE, the UK, Uruguay, the USA, Venezuela, and Vietnam.

Work as an Editor, Administrator, and Textbook Author

Nunan’s authorial record is all the more surprising, given that he has held so many administrative posts and has worked broadly as an editor and textbook writer.

Nunan’s administrative work started in Australia, where he first served as the founding director, National Curriculum Resource Centre for the Adult Migrant Education Program from 1984 to 1988. In 1986, he added to those responsibilities the role of the director of the Australian National Language Curriculum Project. When he moved to Sydney he took up the post of associate director, National Centre for English Language Teaching and Research, which was housed at Macquarie University, a position he held from 1989 to 1994. He was also the director of the Macquarie University ELICOS (English language intensive courses for overseas students) program from 1989 to 1994. In 1994 he moved to Hong Kong, where he worked as the director and chair professor of Applied Linguistics, The English Centre, University of Hong Kong until 2007.

In 1996, Nunan undertook a new venture when he became the dean of the Graduate School of Education, Anaheim University—a completely online university which offers a master’s degree in TESOL, among other areas of study. For a time he was acting president of Anaheim University before becoming its academic vice president in 2008.

Nunan also has substantial editorial experience, having served as an editor of several volumes and as a member of the editorial boards of several scholarly journals. In addition to those titles mentioned above, his edited books include a volume on teacher research, one on qualitative research in language education, one on teaching listening, a volume on language awareness, a collection of language learners’ autobiographies, a volume on identity and language learning, *The Cambridge Guide to TESOL*, and *Practical English Language Teaching* (Nunan, 2003), which became the parent volume to a series of books. (See “Suggested Readings.”)

At the time of this writing, Nunan’s editorial board service includes the *TESOL Quarterly*, *Australian Association of Applied Linguistics Journal*, *Prospect: The Australian Journal of TESOL*, *JALT Journal*, *Language Teaching Research*, *Korea TESOL Journal*, and *The Asian Research Journal*.

In many parts of the world, Nunan is best known to teachers and English language learners as the author of EFL and ESL textbooks. As of 2008, over 800 million copies of his textbooks had been sold. These include *Foundations of Reading I and II* and *EAP Writing Course*, both published by Chulalongkorn University Press in Bangkok; *What Do You*

Think? Communicative Learning Tasks (published by the Language Press in Adelaide); and *The Australian English Course* series (with Jane Lockwood and Sue Hood), published by Cambridge University Press. The series entitled *Atlas: Learning-Centered Communication* and the *Expressions* series were published by Heinle and Heinle in 1995 and 2001, respectively. The *Listen In* series and the *Speak Out* series were published by International Thomson. The *Speak Out* books later appeared in Thai editions and the *Go For It* series appeared in a Chinese edition. The *Expression* series was released in both Thai and Chinese editions, and *Go For It* was also published in a Taiwanese version.

Honors and Awards

David Nunan has received many awards. Some are from individual universities and others are from organizations.

His university honors include the Distinguished Scholar Award at the University of the Pacific in California (1986), the Lansdowne Scholar at the University of Victoria in Canada (1997–8), being named a distinguished scholar at Temple University, Japan (1989), and honorary professor of education, University of New South Wales (2009–14). He won the 40th Anniversary Convocation Medal for Outstanding Alumni Achievement, Flinders University, Adelaide, Australia (2006). He serves as a distinguished visiting professor at both the University of Stockholm and at Chulalongkorn University in Bangkok. In 2007, Nunan was named to the former students' Hall of Fame, St. Stanislaus' College, Bathurst, Australia.

Other honors include a Citation for Services to English Language Teaching awarded by the United States Congress in 2001. Heinle and Heinle publishers honored him with the TESOL Lifetime Achievement Award in 2003. He was listed in *Who's Who for Australia* in 2006, the same year he was a delegate at the Australian Prime Minister's Invitational Conference for 100 Prominent International Australians.

Nunan served from 1991 to 1995 as Australia's representative on the governing board of the Regional English Language Centre in Singapore. He was a member of the Board of Directors, and subsequently served as the President, of the international TESOL association (www.tesol.org). He is also an elected member of the Board of Trustees of the International Research Foundation for English Language Education (www.tirfonline.org). Further information about his life and interests can be found on his personal website (www.davidnunan.com).

Organisation Internationale de la Francophonie

GEORGES DANIEL VÉRONIQUE

In 1946, the French Fourth Republic (1946–58) replaced the defunct French Empire, and the Union Française (French Union) granted French citizenship and political representation to its colonies in an effort to maintain them under its control. The French Fifth Republic (1958), created in the turmoil of the decolonization process, in an attempt to forestall the move toward independence of its colonies, replaced the French Union with the Communauté Française (French Community). Eventually, the Organisation Internationale de la Francophonie (henceforth OIF; www.francophonie.org) emerged in the 1960s, in the wake of the decolonization process that had led to the dismantling of the French Community. The impetus for the founding of the organization came from former colonies wanting to retain their association with France. This entry provides some information on the historical background of the OIF, explains its gradual growth and the development of its policies, and assesses its present contribution.

The term “francophonie” was first used by geographer O. Reclus in 1880 when he attempted to calculate the number of inhabitants of the then expanding French colonial empire (Reclus, 1886). After the failure of the French Community at the end of the 1950s due to most of the participant countries claiming independence from France, major political figures of the newly independent countries who had served in the French Parliament, albeit as French ministers under the French Fourth Republic, such as Léopold Sédar Senghor (Senegal), Habib Bourguiba (Tunisia), or Hamani Diori (Niger) propounded a new form of multilateral relation between France and its former colonies. This new relationship was premised on a shared language, a community of culture and on cultural cooperation, which they named “francophonie,” adopting Reclus’ neologism.

The initiative taken in 1962 by Senghor and his colleagues followed the creation of the Association Internationale des Journalistes de Langue Française in 1952, and of the Conference of Ministers of Education of countries sharing French (CONFEMEN) in 1960 (Léger, 1987). This proposal did not meet with immediate approval from the French authorities. During the same period, the French government responded in its own way to the supposed decline of the French language in the world with the creation of the Haut Comité pour la Défense et l’Expansion de la Langue Française (High Committee for the Defense and Expansion of the French Language) in 1966, a government language-planning body. The growth of *francophonie* as an institution was gradual during the 1970s. In 1961, the Association des Universités Partiellement ou Entièrement de Langue Française (AUPELF) was founded, known since 1998 as the Agence Universitaire de la Francophonie (AUF; www.auf.org), which groups some 750 French-speaking universities around the world. In 1967, the Association of French-Speaking Members of Parliament (Association Internationale des Parlementaires de Langue Française) was created. The general agreement signed in Niamey in March 1970 by 21 French-speaking states (Convention de Niamey), leading to the establishment of the Agence de la Coopération Culturelle et Technique (ACCT), was the first major step in the institutionalization process of *francophonie*.

In 1984, the French government created the Haut Conseil de la Francophonie, its first chairman being the then president of the French Republic, F. Mitterand, and the vice chair,

the president of Senegal, L. Sédar Senghor. However, *francophonie* as a political institution only emerged in 1986, when the first summit of Francophone heads of state, attended by 41 French-speaking states and governments, met in Versailles, France, more than 20 years after Senghor's seminal statement. Since that time, summits of Francophone heads of state have been held every two or three years in various parts of *francophonie* around the world (Mauritius in 1993, Cotonou in 1995, Hanoi in 1997, etc.). In 1997, a secretary general of the OIF was elected and a constitution (Charte de la Francophonie) was voted. This brought a final dimension to the institutionalization process of this transnational body.

The slow development of the OIF over a 40-year period bears testimony to the fact that this institution has evolved from an association of countries related to France by old colonial ties to a postcolonial structure in search of a new policy, striking a balance between the needs and claims for support of third world countries such as Haiti or the Republic of Niger on the one hand and the demands and constraints of rich and influential members such as France and Quebec on the other. The OIF has developed from a cultural and linguistic association mainly aimed at the maintenance of the position of French in the world to a political entity active in promoting the defense of language and cultural diversity in a global world. This evolution is visible both in the constitution of the OIF (the Charte de la Francophonie), modified in 2005 in Antananarivo, Madagascar, and in the role it has played in the adoption of UNESCO's Universal Declaration on Cultural Diversity in 2001 (<http://portal.unesco.org/culture/>).

The OIF is composed today of 56 member states, 14 observers, and 3 associate members. Most of the early members of the OIF belonged at one time or another to the French Empire. However, some well-known Francophone countries, such as Algeria, have remained outside the OIF and recently Rwanda left the organization to join the Commonwealth. Not all Francophone states are de facto members of the OIF, and this organization includes member states which are not historically related to French and France, such as the Cape Verde Islands, Romania, and the Czech Republic. This latter characteristic is an interesting feature of the organization which now plays a role of its own, especially in the domains of sustainable development, of the defense of the diversity of cultural practices, and of endangered languages in Francophone countries.

The language policy of the OIF, in a context of worldwide demographic language competition, is to foster linguistic partnership between French and less commonly taught languages, and to promote alongside the diffusion of French and of vernacular languages, especially in the school systems of Francophone countries. The OIF has developed a language policy that differs in key respects from that of France in the type of programs that receive support and the style of implementation, although of course France retains a strong association with the worldwide promotion of French, because of its policies and practices especially in the cultural and educational domains. However, both the OIF and the French government share the same policy in favor of the plurality of languages and cultures.

The OIF provides an excellent illustration of the institutionalization of a global linguistic space. Although the thrust of its activity is still the promotion of French and vernacular languages, it has moved to be an international forum for democracy and sustainable development in emergent countries.

Ochs, Elinor

INMACULADA M. GARCÍA-SÁNCHEZ

Elinor Ruth Ochs (1944–) is a linguistic anthropologist who has devoted her career to the study of discourse structures and grammar in their larger cultural contexts. Always an avid researcher, theoretically innovative, and committed to cross-cultural ethnography, Ochs has conducted extensive fieldwork on interaction and communicative practices in Madagascar, Italy, Samoa, and the USA. In the USA alone, Ochs has carried out research on topics as diverse as the social construction of scientific knowledge in a physics laboratory, language and social identity, the sociality of autism, language and affect, and the construction of morality as a family discourse practice, among many others. Having accumulated a substantial number of research findings throughout her career, Ochs has made significant contributions to the field of applied linguistics, being perhaps better known for her work on language socialization, narrative, and the analysis of family discourse. A driving impetus in Ochs's work has been her emphasis on the importance of quotidian practices and everyday language use as a rightful locus of inquiry to ground larger concerns about the role of linguistic and cultural practices central to human learning and development throughout the life span.

Ochs's pioneer study of baby talk in the early 1980s among middle-class, white American families was an original breakthrough at a time in which the study of child language was still dominated by experimental procedures. Examining both language *directed to* children and language *produced by* children in its larger social and discourse context, Ochs and fellow linguistic anthropologist B. B. Schieffelin, with whom at that time Ochs initiated a long professional partnership, strongly advocated a pragmatic approach to the study of children's acquisition of communicative competence that entailed the investigation of children's language development not only as grammatical but also as socioculturally appropriate. Ochs and Schieffelin (1979) first established the field of *developmental pragmatics*, which examined, among other things, children's acquisition of conversational competence in context. Realizing, however, that the process of language acquisition is not only affected by the most immediate social and discourse context, but also by larger cultural factors, such as social organization and local belief systems, Ochs and Schieffelin rethought their original formulation of child pragmatic development in favor of a more anthropological and cross-cultural approach to the study of child language. If, before Ochs and Schieffelin, processes of language acquisition were seen as relatively unaffected by cultural factors, and, conversely, processes of socialization (or the transmission of sociocultural knowledge) were thought to proceed as if language (spoken to and by children) mattered little, with the publication of their seminal article, "Language Acquisition and Socialization: Three Developmental Stories and Their Implications" (1984), Ochs and Schieffelin productively brought together these two fields of inquiry to establish a new research paradigm: Language socialization, which documents how novices become competent members of communities of practice *through* and *to use* language. Beyond language socialization, the importance of Ochs's theorizing and analyses of narrative in interaction cannot be underestimated. As one of the most pervasive discourse genres in human social interaction, storytelling has also figured prominently among her interests. In Ochs's model of narrative analysis, most persuasively articulated in the chapter "Narrative Lessons" (2004), everyday narrative

encapsulates all of the central concerns in her scholarly pursuits: narrative as a culture-specific discourse practice by which novices are apprenticed into sociocultural worldviews; narrative as a social activity by which families co-construct identities, social roles, and relationships among its members through situationally organized social interactions; and narrative as a mode of cognition by which people imbue their lived experiences with meaning and coherence. In her theoretical paradigm for the analysis of narrative in interaction, Ochs has advocated a multidimensional approach to narrative, distinguishing two basic types of practice underlying all narrative activity. These two basic practices fall along a continuum in five different dimensions, which include tellership, tellability, embeddedness, linearity, and moral stance.

Ochs's contributions to our understandings of the multiple uses of language in everyday life go beyond specific scholarly findings and the development of research paradigms. With a vigorous commitment to interdisciplinary research endeavors, Ochs has championed throughout her career a more collaborative model for knowledge production in the social sciences. Pooling together resources and scholars from a variety of academic traditions has always been a trademark of her way of working. In addition to her long-time collaboration with B. B. Schieffelin, Ochs has fruitfully joined forces with a number of other scholars, including linguists, conversation analysts, and psychologists, to produce several influential books and edited volumes on language development, discourse, grammar, and interaction, such as *Language Socialization Across Cultures* (with B. B. Schieffelin, 1986), *Interaction and Grammar* (with E. Schegloff and S. Thompson, 1996), and *Constructing Panic: The Discourse of Agoraphobia* (with L. Capps, 1995). The culmination of her long engagement in interdisciplinary research has been the UCLA Center for the Everyday Lives of Families that, with funding from the Sloan Foundation, Ochs established and directed from 2001 to 2010 (www.celf.ucla.edu/). Over these years, the Center compiled one of the richest databases on everyday living among dual-earning, multiple-child, middle-class American families, bringing together linguistic and medical anthropologists, applied linguists, psychologists, archeologists, and scholars of education to examine, from a variety of integrated disciplinary perspectives, daily family interactions and routines.

Ochs is currently a distinguished professor of anthropology and applied linguistics at the University of California, Los Angeles (www.sscnet.ucla.edu/anthro/faculty/ochs/). She also serves in this institution as the director of the Center for Language, Interaction, and Culture (CLIC), a think-tank devoted to training scholars in interdisciplinary methodologies and theories for the study of everyday language use in multiple sociocultural contexts (www.sscnet.ucla.edu/clic/). Earlier in her career, Ochs held academic positions in linguistics at the University of Southern California and at the University of Cambridge. Throughout her professional life, Elinor Ochs has received many prestigious appointments and honors in recognition of her important contributions to the fields of applied linguistics and linguistic anthropology. She served as vice-president and president of the American Association of Applied Linguistics (1995–6), and as president of the Society for Linguistic Anthropology (2001–3). Ochs is a Guggenheim fellow (1984), a MacArthur fellow (1998–2003), and a fellow of the American Academy of Arts and Sciences since 1998. She has also held a number of research and visiting positions internationally, including the Australian National University, Linköping University in Sweden, the Università di Roma, and the Istituto di Psicologia (Consiglio Nazionale delle Ricerche) in Rome, Italy.

With her rigorous analyses of discourse and interaction, Elinor Ochs's scholarly publications are quintessential linguistic anthropology. She has published over 100 monographs, articles, and edited volumes on wide-ranging aspects of the relation between language, culture, and context. In addition to those mentioned above, her books include *Acquisition of Conversational Competence* (1983, with Schieffelin), *Culture and Language Development* (1988),

and *Living Narrative* (2001, with Capps). As a professor of applied linguistics and anthropology, she has mentored and influenced a large number of graduate students who have taken up her original formulations of child language socialization among Samoan and middle-class American families, and helped expand this research paradigm beyond monolingual and relatively homogeneous communities. Language socialization is now a rapidly growing field of inquiry addressing issues of language use, learning, and development across the life span and in a variety of social and cultural settings, including postcolonial and multilingual societies; immigrant communities; educational, religious, and other institutional venues; second language and heritage language socialization; and peer language socialization (Garrett & Baquedano-López, 2002; Duff & Hornberger, 2008). Ochs has left a deep imprint in how many applied linguists currently approach the role of culture in the study of novices' pragmatic socialization, as well as in the analysis of discourse and interaction more generally. Beyond applied linguistics, she has also had a decisive influence in other related fields, including anthropology, education, and cultural psychology.

O'Connor, J. D.

JOHN WELLS

Professor Joseph Desmond O'Connor (1919–98) was one of the leading British phoneticians in the second half of the 20th century. A friendly and informal man, he was known by everyone, students as well as colleagues, as Doc.

Doc was born and grew up in the spa town of Harrogate in the north of England. His paternal forebears had originated in Ireland, and his father had worked as postmaster in Newcastle upon Tyne before moving to Harrogate. His mother was from Yorkshire, and her father had at one time been mayor of Harrogate.

The young O'Connor acquired his secondary education at St Michael's College in Leeds, traveling there daily from Harrogate.

He proceeded to University College London in 1937, where he was awarded a first-class honors degree in French. On graduation, he was drafted into the Royal Armoured Corps of the British Army and by the end of World War II had risen to the rank of Major. In 1945 Daniel Jones, the founder and head of the Department of Phonetics at UCL, whose colleague Hélène Coustenoble had been greatly impressed with O'Connor's ability in French phonetics, was able to arrange an early demobilization for him and to appoint him to the teaching staff of his department.

Doc was not only an excellent phonetician, but also an excellent teacher. Like the other London phoneticians, he was routinely able to recognize and reproduce all the sounds represented in the International Phonetic Alphabet and to teach them to students. As well as French, he also specialized in Danish, a language whose phonetics is notoriously difficult for non-natives. He found, though, that his ability to pronounce it convincingly tended to lead Danes to suppose that he had a much better knowledge of the language as a whole than he really did.

While Jones was something of an austere and private man, whom students could find forbidding, O'Connor and his contemporaries (of whom the most notable was A. C. Gimson) formed a group of colleagues very much at ease with one another and with their students. They set the tone for much of British phonetics in the period 1950–80, building on the foundations laid by Jones but also incorporating the work of American scholars such as Pike on the one hand and Bloomfield and Trager on the other.

Phonetics is a subject that if poorly taught can seem austere and difficult. Doc's lectures were witty and effortlessly informative. His teaching style was friendly and encouraging. His writing was elegant and readable. Particularly influential were his textbooks—*Phonetics* (1973) and, for students and teachers of English as a second or foreign language, his *Better English Pronunciation* (1967; revised edition 1980). *The Times* Educational Supplement called the latter title "a book which can quite safely be said to be the most effective one ever written to help the ordinary learner to improve his pronunciation." English as a foreign language (EFL) specialists also appreciated his *Advanced Phonetic Reader* (1971). After retirement Doc collaborated with his daughter Clare Fletcher to produce an influential English pronunciation practice book, *Sounds English* (1989).

Doc's lasting scholarly contribution is most likely to be his work on the description and teaching of English intonation. Many EFL teachers find this a difficult subject to get to grips with, which is why they tend to neglect it. Nevertheless, it appears that the description of

English intonation differs in important ways from other languages, and that its connection to linguistic meaning is also greater than in many other languages. As a consequence, non-native speakers of English tend not to perceive that part of the meaning which native speakers convey by the use of intonation. It was Doc, with his UCL colleague Gordon Arnold, who succeeded in finding a way to describe English intonation that was also teachable to learners. This included devising a notation system that was elegant and iconic. Their *Intonation of Colloquial English* was published by Longman in 1961, with a second edition, substantially revised, in 1973.

Although he refused to accept invitations to travel abroad to give EFL lectures in other countries, Doc did for many years run the University of London Summer School of English. Here, two or three hundred students from around the world would study English for a few weeks under his genial guidance.

Doc remained on the phonetics staff at UCL throughout his career, being promoted to a personal Chair of Phonetics in 1976. However he declined an invitation to become head of the department, instead accepting early retirement in 1980. For the rest of his life he devoted himself principally to his local cricket club in Ickenham.

A festschrift in his honor, *Studies in General and English Phonetics*, edited by Jack Windsor Lewis, was published by Routledge in 1995.

Doc died of pneumonia at the age of 78.

Odlin, Terence

SCOTT JARVIS

Terence Odlin, PhD, is a well-known and respected American linguist who holds emeritus status in the Department of English at the Ohio State University in Columbus, Ohio. He is also affiliated with the Department of Linguistics at the same university. He is best known for his work on language transfer—or crosslinguistic influence—in both second language acquisition and language contact situations. His best known work is his 1989 book titled *Language Transfer: Cross-Linguistic Influence in Language Learning*, which has long been regarded as the most comprehensive and authoritative book-length synthesis of research in this area. Since the publication of this book, Professor Odlin has also gained a reputation for dispelling erroneous beliefs about types of transfer that have been claimed not to occur (see Odlin, 2006, for an overview of such claims), such as transfer involving syntax (Odlin, 1990) and morphology (Jarvis & Odlin, 2000). He is also known by his colleagues as being uncommonly well read and as having an unusually strong ability to synthesize detailed information and retain it in memory. The result is what many colleagues have referred to as an encyclopedic knowledge not only of transfer research, but also of linguistics and applied linguistics more generally.

Professor Odlin's interest in both theoretical and practical issues in linguistics originally developed through his experience with languages. Beyond his native English, the first languages he studied were Latin and French, but since his years as an undergraduate student, he has also engaged in formal or informal study of several other languages including Spanish, Persian, German, Irish and Scottish Gaelic, Finnish, Swedish, and Polish. His study of languages has, in many cases, coincided with his travels to other countries. He has spent varying and often extensive amounts of time in several countries, including India, Algeria, Iran, Afghanistan, France, Finland, Britain, Ireland, Spain, China, Japan, and Russia. These experiences have deepened his awareness of the multifaceted inter-relationships between language and culture. He describes his passion for languages by emphasizing Bernard Comrie's aphorism that "linguistics is about languages, and languages are about people" (T. Odlin, personal communication, February 15, 2010). Indeed, Professor Odlin's professional interest in linguistics and his personal interest in languages are closely tied together, as his efforts in acquiring a solid understanding of these languages has led him to gain important insights into and intuitions about second language acquisition, which have informed his own research.

Regarding his origins and education, Terence Odlin was born in 1949 in Washington, DC, and he lived in that area throughout his early years, receiving his primary and secondary education in Catholic schools. After graduating high school, he remained in Washington, DC to attend Georgetown University, where he majored in English literature and also took courses in linguistics and the philosophy of language. He graduated from Georgetown University in 1971, and later pursued graduate-level work in linguistics, earning his MA at the University of Texas, El Paso in 1978 and his PhD at the University of Texas, Austin in 1983.

While still a graduate student, he published articles in two major journals—*TESOL Quarterly* (Odlin, 1978) and *Modern Language Journal* (Odlin & Natalicio, 1982)—and within just a few months after completing his PhD, he also published a paper in *Language Learning*

(Birdsong & Odlin, 1983). The first two articles dealt with the second language acquisition of contractions and word classification, and the third article was a review paper dealing with linguistic relativity and the relationship between language and thought. During graduate school, he also developed an enduring interest in contrastive analysis and transfer, but it was not until after completing his PhD that his own research projects began focusing on crosslinguistic influence. During the mid-1980s, he decided to conduct a comprehensive survey of the general state of research on crosslinguistic influence, which culminated in his 1989 book. During that same period of time, he began focusing on specific transfer-related issues, starting with work on word-order transfer in second language acquisition (Odlin, 1990), and then moving to work on crosslinguistic influence in language contact situations—particularly those involving Celtic English (e.g., Odlin, 1991).

In more recent years, Professor Odlin has focused mainly on issues related to the psycholinguistic dimensions of language transfer. Those issues include crosslinguistic influence involving lexical representations (Odlin, 1994a), bound morphology (Jarvis & Odlin, 2000), focus constructions (Odlin, 2008b), and other structural and functional areas of language (e.g., Odlin, 2009b). His work on the psycholinguistic dimensions of transfer has also examined the affective and cognitive (Odlin, 1998), conceptual (Odlin, 2005, 2008a, 2010), and memory-related bases of transfer (Odlin, 2009a), and has considered the relationship between transfer and code switching (Odlin, 2009c), as well as the relationship between transfer and fossilization (e.g., Han & Odlin, 2006).

Over the years, hundreds of researchers have contributed to what we know about language transfer, but Professor Odlin is one of the very few scholars whose concentrated work throughout their careers defines them first and foremost as transfer researchers. He has distinguished himself as an authority and gatekeeper of this area of research, always remaining vigilant of false claims and extreme pendulum swings, and continuously shaping current and future research trends. A good example of the former can be found in Odlin's (2006) reexamination of contrastive analysis, which he argues was too hastily discredited years ago as an ineffective means for predicting transfer outcomes. One of the important points he makes is that, even though it is difficult to predict when transfer will occur, it is just as difficult to predict when it will not occur, as can be seen in the fact that prior claims about the nontransferability of bound morphemes, basic word order, idioms, and functional projections have all been shown to be wrong. Another important point he makes is that predictions about the occurrence of transfer require a fully adequate contrastive analysis based on a wider range of linguistic and cognitive variables than has previously been taken into account. Even though transfer patterns will vary across individuals, Odlin argues that the findings of empirical research in second language acquisition (e.g., on learners' use of articles) can be used to construct relatively accurate predictions concerning the rates of success that groups of learners will experience in acquiring features of the target language—based on the formal and functional similarities that those features share with the learners' native languages.

Good examples of Professor Odlin's contributions to current and future trends in transfer research can be seen in his work on conceptual transfer (e.g., Odlin, 2005, 2008a, 2010) and the relationship between transfer and memory (Odlin, 2009a). His long-term interest in and extensive knowledge of both the historical and current literature on the relationship between language and thought have allowed him to shape the scholarly conversation about conceptual transfer, describing its relationship to the notion of linguistic relativity, clarifying the differences between conceptual transfer and other types of meaning transfer, explaining the types of phenomena that provide the most compelling evidence for it, and calling for moderation in relation both to extreme skepticism toward linguistic relativity as well as to overly strong claims about its effects in second language acquisition, bilingualism, and multilingualism.

Concerning his recent work on the relationship between transfer and memory (Odlin, 2009a), this may represent the beginning of a new trend in transfer research. Even though memory is probably directly or indirectly involved in all cases of transfer, very few researchers have examined this relationship explicitly, and Odlin may be the first to touch on the crucial questions of whether the similarity between a learner's native language and target language affects how much of the target language input the learner can retain in short-term memory, for how long, and how accurately. His results with L2 learners of English whose native languages were Swedish (a language very similar to English) and Finnish (a language very different from English) show that Swedish speakers use more of the available input and use it more accurately than Finnish speakers in a task requiring the learners to produce written narrative descriptions of a film that is silent but nevertheless contains occasional written dialog frames (or titles). One might anticipate that this study will lead to a new robust line of inquiry—including experimental research—on the effects of language distance on learners' ability to retain information in both working memory and long-term memory.

Besides transfer, Professor Odlin has also carried out research in areas of language assessment (e.g., Odlin, 1986) and language pedagogy (e.g., Odlin, 1994b). Additionally, throughout his career, he has also shown a strong interest in issues of general theoretical import to linguistics, such as the nature of universals and their implications for relativism, as well as the implications that both universals and relativism have for second language acquisition. He has a depth of knowledge in several theoretical frameworks, including Universal Grammar, but has remained skeptical of many of the assumptions of Universal Grammar and of the claims that some researchers working within this framework have made about transfer. The theories with which he feels most closely aligned are part of the cognitive linguistics paradigm.

On a personal level, Terence Odlin is known by his friends and colleagues as Terry. He owns a home near the Ohio State University, and enjoys walking to and from work throughout the year. In addition to his passion for language learning and international travel, he also enjoys reading for pleasure and for information on current events, listening to traditional music from various cultures, and dining in cafes and locally owned ethnic restaurants. One of his hobbies and talents also includes photography, as can be seen in his online gallery at <http://people.cohums.ohio-state.edu/Odlin1/graphics/gallery3.htm>. A full list of his publications can be accessed at <http://people.cohums.ohio-state.edu/Odlin1/publist.htm>.

Official Translation

ESTHER MONZÓ

Official translation can be understood both as a translation activity and as a translated document. As an activity, official translation aims to resolve the need for communicating law between different legal systems or different cultural and linguistic systems so that communication is compliant with any needs and standards set out by the public system. As a document, an official translation may be defined as any document which was issued in a language that is not official in the receiving legal system and that has to be translated according to specific requirements, in order to ensure the appropriateness of the translation in the receiving legal system so as to fulfill legal effects.

Legal systems exist throughout the world. They largely rely on words to tell people what they should and should not do and what would happen to them if they did not act accordingly (criminal law). Legal systems also serve as a trustee of the people to ensure, for instance, that citizens are marrying the person they think they are (civil law). To do so, legal systems register people's particulars and offer documents as evidence of what has been registered. In general, legal systems manage an enormous number of document transactions. When communication must take place (as it often does) among systems which use different languages, we may say that the legal systems involved have a case for translation. A legal system cannot stop functioning just because its agents cannot understand a document because of the language in which it was issued. The solution commonly provided is to entrust a selected group of professionals with the responsibility of translating documents according to the principles enshrined by the legal system. These principles may vary from country to country, but "fidelity" and "integrity" are terms commonly found in appointing and certifying formulas for those translation agents.

Who May Become an Official Translator?

Official translators (also referred to as sworn, certified, public, authorized, and court expert translators; see Mayoral, 2003, for a wider range of possibilities) are in charge of translating any document which is meant to have an official effect from any nonofficial language to an official language. To ensure that the work of these translators will satisfy the legal system's requirements, the professionals must overcome some kind of access barrier before working in official settings. Usually a licensing mechanism (such as a public examination) is established by the authorities, but in some cases a university degree (and sometimes subsequent membership in a chartered institution) or an ad hoc appointment by a legal agent who trusts the translator's personal declaration of linguistic knowledge will suffice. In some countries, a professional body rather than a government agency is responsible for either licensing or registering official translators; this then allows the translators to work for official bodies and agencies, such as the courts. Once a translator becomes "official," there is usually an authority (again, either public or professional) that is responsible for ensuring best practice and for punishing noncompliance with legal or professional standards. This means that, in most cases, appointments may be revoked, or renewal, when necessary, may be denied.

2 OFFICIAL TRANSLATION

International institutions represent a special case. They usually have a translation unit and they hire full-time translators on a temporary or permanent basis. They also outsource translations and hire freelancers, whose continuity will depend on their quality and productivity. In any case, to work for these institutions either as an in-house or as an external translator, one must pass an examination. Prior to 2010, passing an examination for the post of permanent translator and receiving an appointment in these institutions granted the translator the status of international civil servant. However, this is no longer the case, and an “appointment” as a translator of official documents is therefore revocable.

Why Are Official Translators Necessary?

Official translators are necessary for the simple reason that all legal agents cannot understand all languages and so need help when working with documents written in languages they do not know. However, the situation is rather more complicated than that. Traditionally, legal systems are divided into two kinds: common law and civil law (we will not refer here to religion-based and communist law). Civil law systems tend to favor prevention over litigation in court, and so there are special agents whose function is to prevent misunderstanding and limit recourse to the courts. This is typically the case with civil law, or Latin, notaries. Their function, usually described as a “precautionary and preventive security” function, is to ensure that parties reach agreement through common understanding and consensus. Thus, the cases where parties need a judge to mediate between them will be reduced and simplified to the terms of the agreement. In civil law systems, sworn translators have a similar function.

Authorities in civil law systems favor these *corps intermédiaires*, representative bodies (Durkheim, 1893), and ask citizens to have documents translated by an official translator in every instance of communication with the authorities (birth, marriage, and death certificates, wills, agreements, etc., to be presented to courts or other government agencies and public institutions). In these systems, both public notaries and official translators are portrayed as neutral parties with interpersonal duties and a heavy responsibility in ensuring communicative success. They are thus, in a way, acting *per procuracionem*, that is, on behalf of the state, when executing their certifying powers. However, any biased or in any other way undue performance must be remedied personally, which means that certified translators may be sued or even prosecuted for any professional action harmful to their clients’ interests.

In this way, the legal system outsources the work and the liability by providing a special agent who will have the responsibility of rendering a translation according to the principles privileged in the legal system. Thus, the document needed, although at first unintelligible to the authorities, will be safely available in a language which is understandable to the other legal agents (it is, however, common practice to attach the original to the translation).

On the other hand, common law legal systems rely mainly on the courts to solve disputes once they arise, and have therefore a strong jurisdictional system. In these countries, the role of official translators is much more prominent before the courts, to ensure that the parties are in equitable conditions before magistrates and judges. And this raises the issue of “mode” in official translation.

What May Be an Official Translation?

When talking about official translation, the expression may be understood restrictively as the translation of written documents or in a broader sense as any interlinguistic mediation

that performs official effects. The latter would include sight translation (documentary evidence in court hearings, documents being read and signed in civil law notary offices), consecutive (court hearings), simultaneous (special court hearings), or liaison interpreting (police interviews, attorney–client communication, court confrontations, or agreement negotiations).

Also, unlike legal translation, official translation is not restricted to any particular subject matter or text type. What defines official translation is the effect the translated document is bound to fulfill. So, if a love letter is to be translated in order to be produced as evidence before the court, an official translation will be needed. Also, any agreements, articles of association, rogatory letters, bills of lading, commercial documents, academic transcripts and university degrees, birth, marriage, or death certificates, among many other text types, typically fulfill official effects in national legal systems and therefore need official translations.

In international organizations, the translations commissioned to translation units may be legislation and other resolutions or standards, letters, reports, notifications, meeting proceedings, complaints from particulars, and also draft documents or even resumés for committees. Therefore, we can say that it is not the subject matter, the text type, or the mode but the translation commission and the setting where the translated document will have an effect that define official translation.

Who May Need an Official Translation?

Any citizen who needs to communicate with the authorities may need an official translation. If a person needs to file or present a document previously issued in another country, it is likely the document will have been issued in a foreign language and will have to be translated by an agent who is trusted by the receiving system (any person authorized as official translator). Members of the general public, but also lawyers representing them, or translation agencies as intermediaries, may therefore seek the services of an official translator.

As said above, it is typically government bodies, agencies and institutions (justice administration agencies and courts, defense agencies, foreign and home affairs departments, etc.) which enact and enforce legitimating mechanisms for translations lodged by citizens. However, those agencies and institutions also require translations for official purposes. In countries with more than one official language, it is common practice to hire staff translators in parliaments, government departments, courts, and town halls who will translate legislation, written questions to bilingual or multilingual parliaments, resolutions and notifications which are to be published in official gazettes, letters, memos, reports, meeting minutes, and so forth, and any document that has to be registered in a public registry or made available to the public; that is, any document which will perform an official effect.

International law enshrines the right of the individuals to use their languages, especially when faced with charges (notably, article 6 of the European Convention for the Protection of Human Rights and Fundamental Freedoms and article 14.3 of the International Covenant on Civil and Political Rights; Council of Europe, 1950; United Nations, 1966), and governments are obligated to establish mechanisms to ensure compliance with this right.

International institutions usually provide translations of public documents in the languages having official status in the institution (for instance, within the United Nations, 6 languages are considered official, and in the European Union, 23). However, committee documents are not always translated into all the official languages, but only into the “procedural” languages. (These depend on particular needs, but as an example the EU employs three languages as procedural languages: English, French, and German.)

Who May Perform Official Translations?

Although we may think translations should ideally be performed by translators (people who work full time in translation), official translations are rather frequently performed by lawyers or nonspecialists. The issue has been the subject of many debates within the professional community and also in the media and among law specialists. A survey was conducted among EU countries regarding translation and interpreting in criminal proceedings. As a result, some requirements are being enforced in such proceedings for both interpretation (article 2) and translation (article 3; European Parliament, 2010). Although similar legislation had already been passed in EU and other countries, some features of the new directive deserve to be highlighted.

The directive obligates member states to ensure that the interpretation and translation provided meet quality requirements (“sufficient to safeguard the fairness of the proceedings”; articles 2.8 and 3.9), especially by providing a register “of independent translators and interpreters who are appropriately qualified” (article 5.2), and the training of legal agents involved in criminal proceedings “to pay special attention to the particularities of communicating with the assistance of an interpreter” (article 6). However, as the regulation has been published as a directive, EU countries will still have to pass national legislation in order for these rules to become enforceable. Also, each country will decide on the particulars of the law, so we will have to wait in order to see how the situation will evolve.

In the meantime, there is legislation in the EU and other countries which covers either *ex jure* or *de facto* other producers (to use Bourdieu’s, 1971, term) in the field of official translation; namely, lawyers and nonspecialists, who may be translators, linguists, or others. According to their needs and budget, courts and notaries in some countries may still appoint *ad hoc* official translators and interpreters, and lawyers may invest themselves with the power of certifying translations at will (see Monzó, 2009, for the case of Spain).

The Future of Official Translation

It is likely that the future of official translation will be one in which more and more institutions recognize the importance of translation in communicating the law effectively and safeguarding people’s rights. Official translation has already entered the domain of academic research (as proven by its inclusion as an entry in this encyclopedia), and training programs increasingly provide specific knowledge and skills for translation and interpreting in official settings. The responsibility which falls on the shoulders of official translators will be increasingly supported by training institutions, professional bodies, and, finally, the user of official translations.

O'Halloran, Kay L.

MICHAEL O'TOOLE

Associate professor Kay O'Halloran (1958–) is the founding director of the Multimodal Analysis Laboratory of the Interactive and Digital Media Institute (IDMI) at the National University of Singapore (NUS), where she has been a member of the Department of English Language and Literature since 1998.

O'Halloran is one of a small but distinguished group of physical scientists and mathematicians who discovered early in their teaching career the need for a sophisticated model of discourse analysis for their discipline, and turned to the theories of M. A. K. Halliday and his colleagues in systemic functional linguistics (SFL) to meet that need. She has repaid her debt to SFL with interest.

After graduating from the University of Western Australia (UWA) with a BSc in mathematics, she taught the subject for some years in high schools in the city and country towns of her home state before achieving first class honors in a BEd in the Graduate School of Education at UWA.

Early in her life she developed a strong social conscience and became aware of the inequities of the secondary education system—even in a “value-neutral” field like mathematics—in Australia and the Western world in general. One way of assessing, and perhaps curing, those inequities was to analyze what happens in the mathematics classrooms of high schools serving different socioeconomic groups. She therefore undertook a PhD study at Murdoch University, also in Perth, Western Australia, where there was a strong program in SFL and critical discourse analysis (CDA). Not content, however, to observe classrooms, teacher and student behavior, and their interactions, she made video recordings of teachers' speech, blackboard work, gestures, and speech rhythms in the classrooms of both private and state schools in contrasting suburbs. She then subjected these to a rigorous linguistic and multimodal analysis, which proved her hypothesis that private schools enjoy a rich curriculum, a degree of teacher competence and student motivation, and a shared discourse that gives them a major advantage both in learning the subject and in passing examinations.

A major problem in establishing patterns in CDA has been the richness, complexity, and sheer amount of language being analyzed. O'Halloran realized early in her graduate studies that computer programming could speed the process of analysis and reveal patterns of meaning making across the three meta-functions of language that were unavailable to those restricted to manual transcription and analysis. She therefore developed with a colleague, Dr Kevin Judd from the School of Mathematics and Statistics at UWA, one of the first software programs for SFL analysis and published it on CD (O'Halloran & Judd, 2002). This has been regularly updated and is highly valued and widely used by SFL specialists.

After completing her PhD, O'Halloran tutored for one year at Murdoch University before spending a period as a postdoctoral fellow at Martin Luther University in Halle, Germany. In 1998 she moved to the Department of English Language and Literature at the National University of Singapore. She was one of the main teachers in SFL in that department, but also raised the institutional support and funds for a multimedia laboratory, the Laboratory for Research in Semiotics, which quickly became a focus for the fast-developing international field of multimodality. The Multimodal Analysis Lab, which is a university-level

research lab in the IDMI, was established on her initiative and under her direction in 2007. It hosted a major international conference on multimodality in 2008 and has active links with university departments and institutes worldwide. O'Halloran's own research work and that of the team of linguists, computer scientists, and IT specialists she has assembled have produced a rich flow of publications and a keen school of MA and PhD students. She has also attracted major research grants from funding bodies at NUS, the Singapore National Research Foundation, and the US Air Force Office of Scientific Research to contribute to the digital humanities, whereby social scientists use interactive digital media technologies and scientific visualization techniques to develop new paradigms for social science research.

O'Halloran's publications include books on mathematical discourse (2005) and a multimodal approach to classroom discourse (in press), and collections of papers by herself and colleagues on multimodal discourse analysis (O'Halloran, 2004; O'Halloran & Smith, 2011). She has demonstrated that mathematical discourse, whether an equation, a string of symbols, a graph, a proof, a diagram, or a textbook page, should be—and is—treated like a picture as well as like a piece of linear text, that is, with the right as well as the left hemisphere. It can therefore be analyzed both with the tools of SFL and with the related tools of multimodal researchers (O'Toole, 1994; Kress & van Leeuwen, 1996). She has also developed the important concept of "inter-semiosis" in mathematics and science, whereby grammatical metaphor is matched by semiotic metaphor in nonverbal modes such as diagrams, formulas, and gestures (O'Halloran, 2005, in press). O'Halloran is a member of the editorial board for the online *SemiotiX* bulletin, which provides information about state-of-the-art semiotics research.

It would be doing O'Halloran an injustice not to mention her teaching skills. She inspires her students and colleagues with fresh ideas, always has time for their contributions and problems, and networks enthusiastically within NUS and internationally on behalf of her peers as well as herself. Over the period when she was teaching in the Department of English Language and Literature at NUS she consistently scored top ratings in student feedback surveys. The dynamics of classroom discourse is not just a subject for academic study: It is her practice.

Ohta, Amy Snyder

YUMIKO TATEYAMA

Amy Snyder Ohta (1962–) is best known for her application of Vygotsky's sociocultural theory to second language learning and development. She is also widely recognized as one of the first scholars who conducted extensive research on the development of interactional competence of adult learners of Japanese through microanalysis of classroom interactions.

Ohta was born in Ohio, but grew up in California. She got a BA in Psychology from Wheaton College (Illinois). Her MA in teaching English as a second language and PhD in Applied Linguistics are from the University of California at Los Angeles (UCLA), where John Schumann and Elinor Ochs served as advisors. Ohta is currently associate professor in the Department of Asian Languages and Literature at the University of Washington (UW), Seattle. Prior to her 1995 appointment at UW, she taught at California State University, Los Angeles (1993–5) and was a visiting assistant professor at Columbia University (Summer, 1998, 2001). Ohta became interested in second language acquisition through her own learning of Japanese while working under Japan's Ministry of Education as a Monbusho English Fellow (1984–6) and her subsequent study at International Christian University in Tokyo (1986–7).

While much of Ohta's work considers second language (L2) learning and development through a Vygotskian framework, language socialization theory and her graduate training in discourse and conversation analysis under Emmanuel Schegloff have had strong influences on her research. Ohta's dissertation examined teacher talk and learners' pragmatic development in L2 classrooms from a language socialization perspective (see Ohta, 1994). In Bräuer (2004), Ohta notes that in her dissertation data students' voices were not recorded well when they engaged in pair or group work because only two microphones were used—one for the teacher and one for the class. This led her to use clip-on microphones for students in subsequent studies (e.g., Ohta, 1995, 1997, 1999, 2001a, 2001b, 2005a, 2008) to capture interactions between students. Using interactional data, Ohta (1997, 1999) examined the pragmatics of learner classroom language. Ohta (1999) investigated the role of interactional routines in the socialization of L2 interactional competence in adult learners of Japanese. Her study revealed that both active and peripheral participation in the IRF routines contributed to an increase of learner use of follow-up expressions, including assessment. That is, while the third turn (feedback) in the IRF structure is usually taken by the teacher in the teacher-fronted instruction, learners use the third turn successfully when they engage in pair work. At a time when the IRF was generally regarded as problematic, Ohta demonstrated how this routine provided a scaffold allowing learners to develop interactional competence.

Examining learner–learner interactions closely drew Ohta more toward the zone of proximal development (ZPD) and sociocultural theory. While Vygotsky was concerned with the cognitive growth of children, Ohta applied the ZPD to the process of learning a second language through social interaction. Supporting Ohta further in this endeavor was her involvement in a research group (Sociocultural Theory and Second Language Learning Research Working Group) led by James Lantolf whose members were interested in using a Vygotskian framework to understand L2 development and cognition (see Lantolf &

Thorne, 2006). Ohta presented her work at the second gathering in 1995 and participated annually through 2000.

Ohta (1995, 2001a) rephrased Vygotsky's (1978) definition of the ZPD in order to suit the L2 learning context better:

For the L2 learner, the ZPD is the distance between the actual developmental level as determined by individual linguistic production, and the level of potential development as determined through language produced collaboratively with a teacher or peer. (Ohta, 2001a, p. 9)

Language is the mediational tool relevant to thinking, learning, and other cognitive processes, and the ZPD describes how learning may occur through socially mediated processes such as peer interaction.

Ohta (2001a) is significant in a number of ways. It is the first single-author volume using a Vygotskian sociocultural framework in analyzing classroom L2 data. In particular, her analyses of private speech reveal that learners use private speech for various purposes such as problem solving and hypothesis testing, and that even when students may seem, to a casual observer, to be passive, they may be actively engaged in learning processes. Further, the analyses of peer interactions show that both stronger and weaker students benefit from collaborative activities. With regard to pragmatics, Ohta proposes a developmental sequence of listener responses (i.e., from acknowledgment to alignment) based on her analyses of learner data (see also Ohta, 2001b).

Ohta continues to examine learner language development from a sociocultural perspective, expanding to other topics that she did not touch upon earlier. In her coedited book (Mori & Ohta, 2008), Ohta (2008) focuses on laughter in classroom interaction and its function in discourse. She shows that laughter reveals not only affect but second language comprehension, providing insight into L2 developmental processes. Ohta (2006, 2010) considers the ZPD from a broader perspective, examining learner interviews to see how the ZPD applies to language learning experiences. While Ohta (2006) shows that adult learners develop the ability to manage ZPDs to optimize their language development, Ohta (2010) focuses on limitations of social interaction for language learning and how learners overcame such difficulties. Further, using cognitive and sociocultural perspectives, Foster and Ohta (2005) investigate negotiation of meaning during classroom interactive tasks.

Lastly, in terms of pragmatics, Ohta (2005b) considers applicability of the ZPD to inter-language pragmatics research and instruction by examining three published interventional studies on pragmatics learning, including Takahashi (2001). Ohta discusses the possibility of explicit instruction functioning as a mode of assistance in Takahashi's study. As Ohta notes, what learners can do with or without assistance and how assistance can be provided to help learners notice the gap and maximize their learning are all relevant issues in designing pragmatics instruction and research. Both researchers and practitioners alike will benefit from her pedagogical suggestions for designing and implementing tasks for collaborative work (Ohta, 2001a).

Oller, John W., Jr.

APRIL GINTHER

The work of John Oller (1943–) in the 1970s and 1980s contributed greatly to the emergence and recognition of language testing as a discipline within the field of applied linguistics. A prolific writer, author of six books, more than 230 published articles, and coauthor/editor of 10 collections, his work includes examination of a wide range of topics related to language testing, intelligence testing, communication disorders, and other subjects. Characteristic of his work is a theoretical orientation emphasizing semiotics, the study of signs and symbols, and the pragmatics of knowledge, beliefs, and expectations of language users in the contexts of ordinary experience. In addition to his contributions to theoretical discussions of testing methods and the nature of language proficiency, Oller is recognized as a proponent of innovative teaching methods. *Methods That Work: A Smorgasbord of Ideas for Language Teachers*, edited with Richard-Amato in 1983, remains a classic attesting to the advantages of distinctly pragmatic approaches, followed by the 1993 version generalizing the application of pragmatic approaches to first language acquisition and the teaching of literacy.

Oller's explication of *pragmatic naturalness criteria* addresses the quality of the instruments and methods used to measure language proficiency, defining a *pragmatic test* as "any procedure or task that causes the learner to process sequences of elements in a language that conform to the normal contextual constraints of that language and which requires the learner to relate sequences of linguistic elements via pragmatic mappings to extralinguistic contexts" (1979, p. 38). Based on the pragmatic naturalness criteria, a good test, or any valid testing, assessment, or teaching method, invokes the learner's *pragmatic expectancy grammar*, described as the psychologically real system that links, relates, or maps the characteristics of language to knowledge about the context in which an utterance occurs. The idea of *expectancy*, a critical notion in Oller's arguments, is related to the gestalt notion of *closure* through which human beings solve problems by supplying missing elements. As Oller points out, whether completing a pattern, solving an equation, or communicating with another person, it is always possible to predict partially what will come next in any given sequence of elements: the more accurate the expectations, the more efficient the problem solving.

Oller's work contributed to the shift away from discrete-point language testing to assessment methods he identified as integrative. Drawing on and developing Carroll's (1961) original distinction, Oller described discrete-point and integrative language tests as opposite ends of a continuum. He explained, "The concept of an integrative test was born in contrast with the definition of a discrete point test. If discrete items take language skill apart, integrative tests put it back together" (1979, p. 37). While discrete-point tests purport to focus attention on one isolated element of grammar at a time, integrative tests require access to meaning through deeper linguistic resources. By focusing the examinee's or learner's attention on surface elements of grammar, discrete-point items were less effective in engaging the deeper grammatical system and thereby failed to assess how the learner would use language in ordinary contexts of experience.

While discourse-based testing procedures Oller identified as integrative included cloze procedures, dictation, oral interviews, and composition, it is important to keep in mind

that the distinction that Oller was making was not one that relied on the surface characteristics of any item format. He recognized that in practice, the most discrete items require some integrative skills and the most integrative procedures always demand use of surface forms that can be scored as if they were more or less discrete items. He also noted that multiple-choice items do not necessarily constitute discrete-point tests. For example, the abilities required to identify the best alternative answer on a reading comprehension test nearly always lean toward the integrative rather than the discrete end of the continuum. Nor is it necessarily the case that an integrative test requires that sources of information be integrated across different modalities or skills (e.g., listening and reading), although particular integrative tasks may do so. The desire for clarification of these points lead to one of the more interesting and protracted debates that has taken place in language testing to date.

Oller's argument that discourse-based cloze tests (Oller & Conrad, 1971; Oller, 1972; Chihara, Oller, Weaver, & Chavez-Oller, 1977; Oller, 1979) assess abilities for examinees to use deep grammatical constraints was challenged by researchers (Alderson, 1979) who argued that the selection of the words needed to fill deletions could be successful based solely on information available within five to seven words on either side of a deletion. If cloze tests measured only such short-range grammatical constraints, the method was flawed as a measure of deep and general proficiency. Bachman (1982) also argued that cloze tasks based on random deletions may not systematically target long-range discourse constraints, and others rejected the method on the basis of their acceptance of null results comparing sequential versus scrambled cloze passages (Shanahan, Kamil, & Tobin, 1982). Given that null results are never a satisfactory basis for the rejection of any empirically testable hypothesis, the perceived importance of these findings was challenged (Cziko, 1983) and many ensuing studies investigated deletion procedures and scoring procedures, with respect to short- and long-range discourse constraints, as well as individual and group effects using a variety of statistical methods and fundamentally different experimental designs.

Studies showing the impact of long-range constraints on random-deletion discourse-based cloze tasks were actually replicated in all cases where appropriately sensitive (powerful) designs were used. Reported null contrasts, on the other hand, comparing scrambled versus sequential texts across different texts and groups of examinees, failed to incorporate the necessary counterbalancing of within- and between-subjects variance, order effects, and differences across the selected texts themselves. All those variables and interactions between them can be controlled in an appropriately counterbalanced repeated-measures design, but where such counterbalancing was omitted, the contrasts of interest between sequential versus scrambled texts were commonly (almost always) swamped, rendering the effects of long-range discourse constraints on specific items statistically insignificant. However, with more subtle repeated-measures designs, it was demonstrated that both short-range and long-range discourse constraints (certainly ones ranging beyond 50 words) are tapped by standard, random-deletion approaches to cloze test construction (Oller & Jonz, 1994; Jonz, 1987). Later, it would be shown on a strictly logical basis, confirmed by many empirical studies, that a substantial number of random deletions could not fail to tap long-range constraints (Oller, Chen, Oller, & Pan, 2005; Oller & Chen, 2007).

Statistical investigations of integrative tests, following a principal components analysis suggested by Nunnally (1967), the long-standing argument for a general factor of intelligence first noted by Spearman (1904), and the growing evidence for the profound connectedness of syntax, semantics, and pragmatics within grammatical systems (Oller, 1970, 1975), led to the simple but ultimately incorrect hypothesis that language abilities might best be represented by a single underlying trait (Oller, 1976). That *unitary trait hypothesis* was challenged and rejected with more sophisticated factor analytic procedures (Bachman

& Palmer, 1981, 1982; Oller, 1983; Carroll, 1993; Bachman, Davidson, Ryan, & Choi, 1995; Kunnan, 1995). The whole controversy that ensued, however, as Stansfield (2008) has noted, focused attention on more sophisticated statistical procedures. Bachman (1990) wrote, "Oller's work, as well as the research it stimulated, firmly established construct validation as a central concern of language testing research and generated renewed interest in factor analytic procedure" (p. 7).

The unitary trait hypothesis was wrong, but an abstracted general factor accounting for the lion's share of the variance in language tests, intelligence measures, achievement tests, and even personality inventories would remain as noted by Oller, Scott, and Chesarek (1991) and Carroll (1993). As with the debate surrounding cloze procedure, even within the present decade, the research and discussions generated by the unitary trait hypothesis still resonate. Current large-scale factor analytic studies seldom fail to carry out model comparisons to include (or exclude) a higher-order general factor (e.g., Sawaki, Stricker, & Oranje, 2009). The models that include a higher-order factor typically provide better fits to the data (just as Carroll, 1993, predicted).

Over the last two decades, Oller has continued to study "language acquisition and its relation to intelligence, cognition, social development and their interactions" (Oller, personal communication). His most recent work with the general theory of signs (GTS), elaborated in Oller (2005), Oller et al. (2005), Oller, Oller, and Badon (2006, 2010), and Oller (2010), have led into a more general investigation of sign systems not only in linguistics, but also in genetics, biochemistry, and especially, the amazingly complex and layered immune systems (Oller, 2010).

Oller (2005) explains:

Building on the foundational trichotomy of icons, indexes, and symbols, GTS addresses three interrelated questions in its three component theories: (a) *The theory of TNRs* [true narrative representations] is about how any signs can attain any meaning, (b) *the theory of abstraction* concerns the unpacking and deciphering of signs by infants, and (c) *the theory of systems grammar* examines the properties of the sign systems generated by the prior theories. (p. 119)

Central to GTS is the idea that "in linguistic and genetic terms, successful discovery of language conventions, i.e., language acquisition, and ordinary successful communications in all domains of experience and biochemistry—depend ultimately (and unsurprisingly) on valid representations that are faithfully mapped onto whatever facts they may purport to be about" (Oller, personal communication).

Pragmatic mapping remains central and affords a compelling alternative to strictly semantic and formal (autonomous syntactic) theories of language acquisition, grammar, and language testing. In language testing, the shift Oller encouraged continues away from discrete-point approaches toward integrated performances in contexts broader than those circumscribed by the surface forms or component domains of any particular language-processing task. However, Oller's emphases on processing, episodic organization (discursive constraints), and cognition have been less fully elaborated in current language testing research and theory. It may be the case that in the next decade, processing, cognition, and pragmatics will receive greater attention. In any case, Oller's legacy will remain one that will continue to be influential while providing rich opportunities for further development.

Online Communities of Practice

ELIZABETH HANSON-SMITH

Communities of practice (CoP), a term coined by Lave and Wenger (1990), describes the kinds of informal knowledge building and sharing that occur in workplaces characterized by apprenticeships. CoPs are characterized by a common *domain*, a relatively narrow area of expertise or purpose; a *community* where newcomers and experts alike can build and share expertise in social interactions, both those that further the work at hand and those that develop as humans socialize with each other on a relatively frequent basis; and finally, a *practice* (*praxis* as opposed to theory), that is, the more or less conscious effort to build a repertoire of knowledge over time by developing skills in the field hands-on (Wenger, 2004). Lave and Wenger found significant evidence that interactions not directly related to this matter furthered the cooperativeness and efficacy of group endeavor. Thus *situated learning* in a CoP can be both unconscious and deliberate, but usually it is directed by the individual within a social context. This type of learning contrasts with the classrooms and curricula of educational systems, which involve knowledge that is abstract, out of context, and other-directed. Lave and Wenger's (1990) concept of situated learning is usually seen as harking back to Vygotsky's theory of *social cognition* (1978), social and cognitive development within a zone of proximal development; that is, children achieve their highest cognitive development by engaging in social behaviors, with adult guidance and in peer collaboration, or both.

Over the late 1990s and first decade of the 2000s, Wenger's further thinking about CoPs (1998, 2004) extended the meaning of the term to include online communities and interactions at a distance, rather than just in a physically confined workplace. The concept of *online CoPs* included the types of interactive environments fostered by then new technologies, such as electronic lists, online bulletin boards, or forums; and has since expanded to the social networking applications, such as blogs, wikis, Facebook, Twitter, and so forth. Wenger (2004, p. 2) was quick to point out that the type of casual socialization most usually found in these Web 2.0 applications does not really pertain to CoPs, which require a search for knowledge in a particular field and the application of what is learned over a period of time. However, the capabilities of such applications for social networking are of importance in developing online CoPs, for they enable groups to socialize casually in ways similar to those of local, land-bound communities and when used to share knowledge, to develop a personal learning network (see, e.g., <http://twitter.com/grahamstanley>). Of particular interest to the field of applied linguistics, CoPs for distance education allow the extension of learning around the globe.

By analogy to the CoPs of workplaces of business and industry (see Brown & Duguid, 1991), schools are seen to provide a potential locus for CoPs in which Wenger's criteria of domain, interaction, and practice are met. The concept of educational CoPs has converged with the ideas of Dewey (1916) and is often linked to Seymour Papert's version of *constructionism* (Papert & Harel, 1991), a pedagogical theory that suggests that students learn best through hands-on activities, particularly when students can mix their abilities in collaborative projects; and to *cognitive constructivism*, Piaget's theory that knowledge is developed by accommodating new experiences to one's internal representation of the world (see Piaget, 1951). Teachers adhering to these pedagogical principles are encouraged to form

student working groups and to allow their learners to interact more freely than in a traditional classroom while engaging in, for example, extended content-based projects. In common parlance, then, classrooms and student groups are often referred to as “learning communities” (see Smith, MacGregor, Matthews, & Gabelnick, 2004). Recently, interfaces such as Facebook and Twitter (and other micro-blogging tools accessible from both mobile phones and computers) have been used as a means to facilitate informal communications among students (see articles cited in Newgarden’s 2009 annotated bibliography).

Hanson-Smith (2006) has pointed out that classrooms and student groupings have little time or opportunity to grow into the kind of long-term social arrangements that CoPs in the workplace offer. Students in the United States, for example, may be from differing cultural groups and may perceive their grouping as an artificial contrivance for the purposes of the teacher and not for their own productive efforts. Elsewhere, in countries where English is taught as a foreign language, grouping students may be counter to cultural expectations of classroom authority and “normal” teaching procedures. In any case, classroom “communities” rarely endure beyond the immediate project or academic semester. Human social bonds develop slowly, and the school environment is not generally conducive to the “peripheral participation” (where newcomers can lurk or observe experts until they feel ready to contribute) that is expected in an apprenticing situation (see Lave & Wenger, 1990). However, in the online environment, students may be more willing to explore social relations with peers from exotic locations and learn to work in a virtual community, as in, for example, the GLOBE science projects (www.globe.gov/) and iEARN creative collaborations (<http://iearn.org/>). For educators, the Internet proffers extended contact in a professional interest group that may be more congenial to their needs than teachers in their own school or district. This fact is of particular importance for teachers who are interested in using technology in their classrooms (blended learning) or for distance learning, a growing field of education in the early 21st century, but one where only a few teachers in a given school may seek to expand their knowledge (see Hanson-Smith, 2006; Stevens, 2009). Faced with anxiety in their colleagues about using technology, Internet- and computer-savvy teachers often find themselves shut out of any meaningful informal expansion or exploration of their technology skills and potential. An online CoP can provide instant help, expertise, long-term apprenticeship in a safe social setting, and perhaps most importantly, emotional support for teachers isolated from their technological peers.

Long-standing professional electronic lists might be considered a rudimentary type of online CoP; however, they often lack the social networking that ensures longevity and collaboration. A certain level of trust must be attained before newcomers will ask seemingly “dumb” questions. More recently, many CoPs seem to thrive by using online venues, such as Yahoo Groups or Google Groups; in Yahoo’s category “Schools & Education,” there are over 4,700 groups for homeschoolers alone. Other groups include English teachers living in Japan, science teachers in Sri Lanka, Waldorf and Montessori educators, and even a group specifically for discussing communities of practice (<http://groups.yahoo.com/group/com-prac>). The capabilities of such groups for archiving documents and photos, bookmarking, e-mail search and threading, instant messaging, and so forth, make them ideal venues for building and supporting online CoPs. Mobile and social networking technologies are important for group dynamics, but a CoP must also allow time for thought and reflection on praxis, hence the importance of Internet archiving.

The Webheads in Action offer a concrete model of a successful online CoP. Their domain is educational technology for language teaching and learning. An e-mail list (http://groups.yahoo.com/group/evonline2002_webheads) is their fundamental form of communication, but individuals exploring the praxis of educational tools have also set up many other venues for communication: individual blogs and wikis to reflect on their own practice, a social bookmarking group, numerous webpages recording collaborations with each other’s

classes, a Twitter homepage, a Google Wave, group tagging, and so on. An index page (<http://www.digibridge.net/teresadeca/webheads/wia-index.htm> [2002–10] and <http://wiaindex2010.pbworks.com/w/page/10642872/FrontPage> [2010 onwards]) collects links to the varied Webhead experiments, personal homepages, presentations, and papers. An exemplary feature of this CoP is the building of community through synchronous communications during a regular weekly drop-in meeting at Tapped In (www.tappedin.org/), a text chat venue specifically for teachers and home to a number of other professional educator communities. Live chatting allows members to socialize in a more personal way than through the e-mail list. The group will sometimes proceed to other meeting spaces with Internet telephony or voice and video conferencing capabilities.

As far as praxis, Webheads share rich online lives. When a member of the group discovers a new online tool, others are quick to experiment with it. When someone asks a pedagogical or technological question, others respond with answers and citations. Generally, group members collect all answers or experimental results online, for example, in a blog or wiki, and report back to the group so that the information can be archived. Frequently, Webheads will call upon each other to participate in a class-to-class collaboration, or to serve as an audience when students or peers present projects online. Over the last several years, Webheads have been offering their own free biennial online conference (see www.WebheadsinAction.org/) so that members have a chance to show their recent work to each other and a global audience. Webheads also regularly offer a session in the Electronic Village Online, a project of TESOL's computer-assisted language learning interest section (<http://evosessions.pbworks.com/>), to allow newcomers to technology an apprenticeship with the educational tools most frequently used by Webheads. Thus the furthering of specific knowledge about their domain takes place in a socially situated learning space created through Internet and mobile technologies.

The formation of online CoPs has some degree of application to the distance learning of languages, where short-term collaborative groups can be successfully instituted. However, community building holds a more significant place in the training and further professional development of educators. Teacher communities have been suggested for the school workplace (Martin-Kniep, 2004; Lieberman & Miller, 2008), and as online support for novice language educators as they leave their teacher training institution and scatter to new job sites (Dahlman & Tahtinen, 2006). Of even greater benefit, perhaps, is to provide experienced teachers with the rewards of contact with their peers in other parts of the world, particularly those in the rapidly changing domain of online distance education. Internet and mobile technologies offer multiple opportunities to continue to learn from other professionals worldwide in collaborative communities. Increasingly, institutions of teacher training and professional associations around the globe are taking advantage of these useful resources to foster online CoPs.

Online Intercultural Exchanges

ROBERT O'DOWD

Introduction

Online intercultural exchange (henceforth OICE) refers to the application since the early 1990s of online communication tools to bring together classes of language learners in geographically distant locations with the aim to develop their foreign language skills and intercultural competence through collaborative tasks and project work. The two best known models for OICE are e-tandem learning and telecollaboration (O'Dowd, 2007). Early reports of OICE projects such as the Orillas Network (<http://www.orillas.org/acte.html>), as well as in-depth research studies, demonstrated the potential of this activity for supporting collaborative learning and developing intercultural awareness. Since then, OICE has come to be considered as one of the main pillars of online foreign language education.

Models of Online Intercultural Exchange

OICE traditionally took one of two forms or models—each one reflecting the principal learning aims prevalent in foreign language education at the time. The first well-known model was e-tandem, which focused on fostering learner autonomy and learners' ability to continue their language learning outside of the language classroom. The second model is usually referred to as the "telecollaborative model" and reflected the emphasis in the late 1990s and early 2000s on intercultural and sociocultural aspects of foreign language education.

In the e-tandem model (O'Rourke, 2007), two native speakers of different languages communicate together with the aim of learning the other's language and messages are written 50% in the target language and 50% in the mother tongue, thereby providing each partner with an opportunity to practice their target language and, at the same time, to provide their partner with authentic input in his or her target language. These exchanges are based on the principles of autonomy and reciprocity and the responsibility for a successful exchange rests mainly with the learners, who are expected to provide feedback on their partners' content and on their foreign language performance. In this sense, tandem partners take on the role of peer tutors who correct their partners' errors and propose alternative formulations in the target language. The role of the class teacher in the e-tandem model is usually minimal. For example, learners are encouraged to take on responsibility for finding their own themes for discussion, correcting their partners' errors, and keeping a learner diary or portfolio to reflect on their own learning progress.

The second model differs from e-tandem in the greater importance it attributes to classroom activity and in the shift of focus from language learning to culture-and-language learning. The telecollaborative model goes to much greater lengths to integrate the online interaction completely into the students' language programs and involves international class-to-class partnerships in which projects and tasks are developed by the partner teachers in the collaborating institutions. For example, students' contact classes are where online interaction and publications are prepared, analyzed, and reflected upon with the guidance

of the teacher. Telecollaboration also places the emphasis of the exchanges on developing cultural awareness and other aspects of intercultural communicative competence, in addition to developing linguistic competence. For this reason, common activities include collaborative research projects comparing both cultures and the analysis of “parallel cultural texts.” For example, Furstenberg, Levet, English, and Maillet (2001) had French and American students engage in comparative studies of the film *Three Men and a Baby* with the French original, while O’Dowd (2006) had students carry out ethnographic interviews with their partners in the USA via videoconference and then write reflective essays on the cultural differences that had emerged during the interviews.

Third-Generation OICE: Telecollaboration 2.0

Recent years have seen a third “generation” or model of OICE emerging which reflects in many ways a more flexible and adaptable interpretation of how online intercultural interaction and exchange can take place in foreign language learning contexts. Described by Guth and Helm (2010) as “Telecollaboration 2.0,” this model focuses not only on the development of learners’ linguistic and intercultural competence but also on the online literacies necessary to learn and to work in today’s information society. Telecollaboration 2.0 allows for a much greater spectrum of possible partners, language set-ups, and forms of interaction. For example, learners are engaged in collaboration not only with other classes of foreign language learners, but also with trainee teachers, students of culture studies, or indeed with native speakers who are not involved in education at all. Projects now commonly comprise complex multilateral rather than bilateral group set-ups and language use is not necessarily bilingual, but can involve the use of a lingua franca or can be multilingual (e.g., language mixing of Romance languages). Finally, as these exchanges now exploit Web 2.0 tools, online interaction is more multimodal in nature, involving communication through combinations of text, voice, photographs, videos, and other formats.

Conclusion

Despite receiving a considerable amount of attention in the literature, it would appear that OICE has yet to achieve a high degree of integration or “normalization” in the area of foreign language education. There are various reasons for this. First, practitioners who organize exchanges often encounter practical barriers such as difficulty in finding partners, misalignment of academic calendars between institutions, differing institutional approaches to assessment and to the use of new technologies in the classroom (Belz, 2002). Other problems which hinder integration include the lack of pedagogical training available for educators, educators’ fear of the extra workload, and, finally, the lack of long-term stability of partnerships with other educational institutions (O’Dowd, 2010).

However, these drawbacks should not deter potential practitioners from an activity which has been found to make valuable contributions to different areas of foreign language education. Research studies have highlighted, for example, its contribution to the development of learner autonomy, linguistic competence, intercultural communicative competence, and more recently, to learners’ online literacy skills. Studies have also focused on the reasons for intercultural misunderstanding and conflict in online interaction (e.g., O’Dowd, 2003). Despite the practical barriers mentioned earlier, the future for OICE is undoubtedly bright. The overall image in recent times is that of a flexible activity which is less tied to a text-based interaction, which no longer reifies the native speaker model as the goal of foreign language learning, and which gives learners greater freedom in their choice of potential partners and communicative tools. Thorne (2010) describes this form of OICE as

“intercultural communication in the wild” (p. 6) and speculates that while this may be less controllable from the teachers’ point of view, the opportunities which it offers for intercultural language learning are compelling.

Online Psycholinguistic Methods in Second Language Acquisition Research

THEODOROS MARINIS

Introduction

Second language acquisition (SLA) research has traditionally used paper-and-pencil tasks, such as grammaticality judgment and completion tasks. In such tasks, participants usually have time to read the whole sentence, they can think and reflect about its form and meaning, and then make a conscious judgment about its grammaticality or how to complete it. This is why these tasks are called offline; that is, the information we get is after the participant has read the whole sentence and has had time to think about it. This is in contrast to online methods that measure how participants process sentences as they unfold word by word or phrase by phrase; that is, these methods measure how participants process sentences in real time.

This entry focuses on widely used behavioral online methods, and will provide a short introduction to four such methods recently used in SLA research to address how second language (L2) learners process sentences in real time. These methods are: (a) word monitoring, (b) self-paced reading/listening, (c) cross-modal priming, and (d) self-paced listening and picture verification. Each method is described with examples from key L2 studies. The final section compares offline with online tasks and discusses the advantages and disadvantages of each of these methods.

Word Monitoring

The word-monitoring task is a dual task. At the beginning of each trial, participants hear a word, such as *cakes*, or they see a picture representing a word, such as a picture of cakes. Then the participants listen to two sentences: a leading sentence that creates a context (Marslen-Wilson & Tyler, 1980) and an experimental sentence. The experimental one most of the time contains the word they heard or saw at the beginning of the trial, as in (1) (Chondrogianni & Marinis, in press).

- (1) Mary really likes to bake. Every day she *bakes* cakes and sometimes cookies and muffins.

Participants are asked to listen to the sentences for comprehension. In addition, they have to press a button in a button box or a key on a keyboard as fast as they can if they hear in the experimental sentence the word that was presented at the beginning of the trial. A computer records whether or not the participant pressed the button and also the reaction time (RT) of the button press.

The word-monitoring task can be used to investigate whether participants can process a syntactic anomaly, as shown in (2) (Montgomery & Leonard, 2006; Chondrogianni & Marinis, in press); a semantic anomaly, as shown in (3); or any other type of anomaly (Tyler & Marslen-Wilson, 1981; Komisarjevsky Tyler, 1992).

The Encyclopedia of Applied Linguistics, Edited by Carol A. Chapelle.

© 2013 Blackwell Publishing Ltd. Published 2013 by Blackwell Publishing Ltd.

DOI: 10.1002/9781405198431.wbeal0884

- (2) Mary really likes to bake. Every day she *bake* cakes and sometimes cookies and muffins.
- (3) Mary really likes to bake. Every day she *drinks* cakes and sometimes cookies and muffins.

The rationale for this task is that participants should unconsciously slow down when they are faced with an ungrammaticality or anomaly. Therefore, if participants process the ungrammaticality, they should show longer RTs in the sentences with an anomaly than in the grammatical sentences. Importantly, the word they are monitoring is not the word that causes the ungrammaticality or anomaly, but the word after the ungrammaticality. Participants do not focus on the grammaticality of the sentence, and therefore their RTs reflect an unconscious rather than a controlled process.

Word-monitoring tasks include also sentences that do not involve the word to be monitored. These are called “catch trials.” In catch trials, participants should not press the button. These trials are required to make sure that the participants do not press the button mechanically and to keep them alert and attending to the task.

Word-monitoring tasks, like other online tasks discussed below, should also include filler sentences. These are sentences of different types that do not follow the same pattern as the experimental sentences. The inclusion of filler sentences aims to avoid participants becoming familiarized with the types of sentences used and becoming aware of the aim of the study.

In addition to filler sentences, online tasks often include comprehension questions. This is to ensure that participants read or listen to sentences for meaning. These questions also provide information about how accurate participants are in comprehending the sentences.

Cross-Modal Priming

The cross-modal priming task is another dual task. Participants have to perform two different tasks that involve two modalities: auditory and visual (Love & Swinney, 1996). Participants listen to a sentence for comprehension, as shown in (4), and at a relevant point in the sentence they see a word (cross-modal lexical priming) or a picture (cross-modal picture priming) on the computer screen. This word or picture is called the target. Then participants have to do a secondary task, which could be naming, lexical decision, or picture classification (e.g., an animacy task), by pressing a button as fast as possible.

Half of the targets are related to a word in the sentence (semantic associates or identical repetitions) (Clahsen & Featherston, 1999) and the other half are unrelated. The targets are presented at a syntactically relevant position, and also at a control position that usually precedes the syntactically relevant one. For example, in (4), used in Felser and Roberts (2007) and in Roberts, Marinis, Felser, and Clahsen (2007), there is a syntactic (filler-gap) dependency between *peacock* in the main clause and the trace/gap (t_i) in the relative clause. Participants have seen a related target (picture of a *peacock*) or an unrelated target (picture of a *carrot*) at the position of the trace/gap (offset of *present*) or at a control position (500 milliseconds earlier).

- (4) John saw the peacock_i [to which the penguin gave the nice birthday present t_i in the garden]

Figure 1 Picture verification for self-paced listening task (reprinted from Marinis, 2007; © Cascadilla Proceedings Project)

in a self-paced listening task (Marinis, 2007, 2008). The sentence either matches the picture or not. An example from Marinis (2007) is provided in Figure 1, with a matching sentence in (7) and a mismatching sentence in (8).

(7) I think / that / the zebra / was kissing / the camel / ... (Active, Match)

(8) I think / that / the zebra / was kissed / by the camel / ... (Passive, Mismatch)

The two sentences in (7) and (8) provide a minimal pair. Until the phrases *was kissing* and *was kissed*, it is unclear whether or not there is a match between the picture and the sentence. The disambiguation is provided in the inflectional suffixes *-ing* and *-ed*. RTs on the mismatch condition are predicted to be longer than in the matching condition.

In this task, the picture can be presented prior to the sentence or simultaneously with it, and can either remain on the computer screen throughout the sentence or can disappear when the sentence starts. Presentation of the picture before the sentence allows participants to make predictions about the sentence that will be proved or disproved when they listen to it. If the picture disappears when the sentence starts, this adds a memory component because participants will have to remember the picture when they verify at the end of the sentence whether or not the picture matches it.

As in self-paced reading/listening, in this task RTs are recorded for each word or phrase, and this allows the researcher to make inferences about how participants process the sentence as it progresses. This is in contrast to the word-monitoring and the cross-modal priming tasks, which record RTs only at one particular position in a sentence, and therefore do not allow us to evaluate the whole sentence. Another difference between the self-paced listening with verification and the word-monitoring and cross-modal priming tasks is that although all three are dual tasks, and therefore require more processing resources than single tasks, the self-paced listening with verification task allows participants to listen to the sentence at their own pace. This makes it easier than the first two tasks.

Comparison Between the Tasks: Advantages and Disadvantages

Offline tasks are easy to set up; they do not require special equipment for data collection; and the data analysis is fast and easy. However, they measure how participants interpret
